One of the most well-known and influential educators in Rome was Quintilian (35–96 A.D.). After training in rhetoric and pursuing a career in law and politics, he was appointed the first state professorship of rhetoric in Rome. Quintilian authored the *Institutio Oratoria* ('Education of the Orator'), a 12-volume series that covered wide-ranging topics in education from preschool to advice for the practicing orator. His advice was that of a distinguished politician and orator regarding the education of boys from upper-class families who were destined to become future leaders. From that perspective, the primary objective of education was to train students to be effective and persuasive public speakers who would then be good public servants. Self-discipline, moral integrity, and social conscience were highly valued attributes. In an age that lacked print media, an esteemed man who could sway public opinion with his oratorical skills held incomparable value for the state. A command of spoken language in conjunction with a background in its literature, history, poetry, music, and philosophy was the mark of a well-educated citizen.

Many of Quintilian's educational principles would be recognized in modern guidelines for practice. Among other things, he advocated that curricular content must be appropriate to the child's ability level (a better predictor for success than age alone); individual differences, both intellectual and physical, among students must be taken into account, with aptitude being an important factor in determining success; a system of rewards to promote learning is more effective than one of punishment; learning cannot be forced, rather, interest, motivation, and persistence are better served through a pleasurable instructional experience; content should be relevant to contemporary situations, and activities should deal with the practical application of that knowledge; and public education is more beneficial than private for the development of social skills.

With regard to language learning in particular, Quintilian suggested that spelling should reflect pronunciation and that games should be used to encourage learning. He advocated the use of wooden blocks in the shape of letters as a way for young children to learn the alphabet and spelling. Above all, he maintained that earlier is better, especially where language is concerned. He recommended that children learn Greek first and Latin second, as the latter would be learned anyway in the context of daily life. Because he believed that learning derives from instruction, he warned that care must be taken to expose children only to excellent and accurate models of language use, both with regard to their caregivers and to the texts they read. Errors, once inscribed on the wax tablet that was the metaphor for the child's mind (Aristotle's *tabula rasa*), were considered difficult, if not impossible, to erase.

Latin Grammars

Aelius Donatus (4th century A.D.) and Caesariensis Priscianus (end of the 5th to the early 6th century A.D.) were Roman grammarians who wrote Latin grammars. Donatus's short grammar, *Ars minor*, was so widely used that any elementary grammar book became known as a 'donat.' It presented the parts of speech in a question and answer format ("What is a noun? A part of speech that signifies by its case a person or thing specifically or generally.") Examples from literature illustrated forms and correct usage. It also contained lists of commonly made errors (alongside the correct forms) and figures of speech. Donatus referred to students' errors as 'barbarisms,' and it is likely that many of them were incorrect spellings based on language they had learned only from dictation, in addition to influences from Vulgar Latin (i.e., the language commonly spoken by the people), which was quite different both from the classical, literary language that students learned in school and from non-Latin dialects. Priscian's grammar, *Institutiones grammaticae*, meant to follow the *Ars minor*, was an 18-book treatise on all aspects of Latin grammar, phonology, morphology, and syntax, filled with quotations from Latin authors. For many students, the examples from Priscian's grammar constituted their only exposure to Latin literature.

The curriculum that Rome had adopted from Greece, namely, grammar, rhetoric, dialectics, mathematics, astronomy, music, and philosophy, remained unchanged for centuries throughout Western Europe. It was a system of education founded on the study of language and designed for students who were already functionally proficient in the language – Greek or Latin – before they began to study it formally.

Education in the Medieval Age

When Germanic tribes invaded, fractured, and conquered the Roman Empire, many of them accepted the culture of Rome and Greece, including Christianity. As a consequence, the Roman church emerged as a dominant influence in Western Europe. The aim of education changed from the development of the educated citizen to the preparation of a man of God, in anticipation of the afterlife. The focus of education turned away from the practical affairs of the world, from sense experience, from physical education, and from external reality. Truth was viewed as absolute: it was not discovered through experimentation but delivered through faith, and it was found only within the Church. Because pupils were inclined toward evil, as a result of original sin, they had to be disciplined and undergo physical punishment to control their evil inclinations.

The spread of Christianity created a conflict between Christian theology and ancient philosophy in education. Liberal thinkers wanted to maintain what was beautiful from the ancient authors, preserving their culture in a Christian form. Theologians were ambivalent in their attitude toward Latin and Latin authors. On the one hand, the Bible and church services were in Latin, so all clergy needed to learn the language. On the other hand, Latin literature, which had served as the model and the method for language teaching, was pagan and a source of possible moral corruption. Because of this, the classical authors were no longer considered appropriate content, especially for young people. Scripture and the writings of the early Church fathers replaced them as models for learning Latin.

Three types of schools predominated during the Middle Ages: the catechetical school, the cathedral school, and the monastic school. Catechetical schools provided an elementary level of education consisting of fundamental doctrines of faith. They were designed for catechumens, that is, possible converts to Christianity, and they provided only what was essential in Latin; namely, the memorization of prayers and scripture passages. The monastic schools, in contrast, trained boys to become monks. They retained the Roman curriculum of the seven liberal arts, divided into the trivium – grammar, rhetoric, and dialectics, or logical argumentation – and the quadrivium – arithmetic, music, geometry, and astronomy. The cathedral schools prepared clergy and sought to provide advanced knowledge of scripture, doctrine, and ritual. This instruction was combined with the study of grammar, rhetoric, literature, geometry, history, and philosophy. Boys who did not intend to become either priests or monks but who wanted a general education attended either the cathedral or monastic schools, where they studied the liberal arts as 'externs.'

Monks were members of a religious order, or community, who vowed dedication to lives of chastity, obedience, poverty, farming, and teaching. They were workers, not contemplatives. The curriculum of the monastic schools, therefore, stressed practical skills. Latin, too, was learned for utilitarian purposes: reading and singing to participate fully in the ritual activities of the church, writing to copy manuscripts (but not necessarily to understand them), rhetoric to be able to teach and preach effectively, and arithmetic to calculate the dates of Easter.

An early church figure, Jerome (340–420 A.D.), having completed a classical education in Rome

and then studied theology, asceticism, Hebrew, and scripture, translated the Bible from Hebrew and Greek into Latin. This was the first Latin bible, known as the Vulgate. It became the official version of scripture for eight centuries. Jerome also founded a monastery and a monastic school in Bethlehem. In a letter dated 403 A.D., he offered advice to a mother on how to raise her infant daughter, much of which can be traced to Quintilian. Jerome stressed the importance of good models and advocated early play with alphabet blocks. He warned against allowing errors to occur and suggested that to ensure accuracy from the very beginning, the mother should guide her daughter's hand as she wrote on a wax tablet or traced letters carved in a board, "so that her efforts confined within these limits may keep to the lines traced out for her and not stray outside of these" (Ulich, 1954: 165). Errors are to be strictly avoided, as "An unused jar long retains the taste and smell of that with which it is first filled" (166). Jerome also advised that the girl learn both Greek and Latin from the very beginning to avoid a non-native-like accent: "For, if the tender lips are not from the first shaped to this, the tongue is spoiled by a foreign accent and its native speech debased by alien elements" (167). Finally, he suggested that the ideal solution would be to send the girl to a monastery.

Another early Church father, Augustine, in his *Confessions*, provided an account of his language-learning experience. He claimed that language developed out of a need to communicate and that he learned his native language by associating sounds and gestures with objects. He then collected these 'signs' and used them to convey his own meanings and desires. Augustine did not know Greek before he went to school and suffered because of it, causing him to hate the language: "The difficulty of learning a strange language did sprinkle as it were with gall all the pleasures of those fabulous narrations. For I understood not a word of it, yet they vehemently pressed me and with most cruel threats and punishments to make me understand it." He compared that experience to learning his first language, without fear or torment, but simply by listening to people talk to him and attempting to convey his own meanings, concluding that "a free curiosity hath more force in children's learning of languages, than a frightful enforcement can have" (147). By his own admission, Augustine loved classical Latin literature, but he criticized the amount of time and effort spent on it and particularly disliked grammar: "men care more to observe the rules of grammar than the laws of God" (149).

The Rise of Universities

Moslem influence during the 11th and 12th centuries, with access to Greek texts in translation, stimulated renewed interest in classical learning. Scholars traveled to Spain and southern Italy to peruse the tremendous libraries that the Arabs had built. In addition, the growth of cities provoked a need for professional training in law and medicine. The university had its informal beginnings where teachers and students came together to learn and debate, much as they had done in Plato's Academy. For their own protection from interference by secular or Church authorities, teachers and students found it necessary to incorporate themselves; hence, the term 'universitas' (guild or corporation). The University of Bologna was the earliest – established in 1088 – and specialized in law; the University of Salerno specialized in medicine, and the University of Paris specialized in the arts.

At the university, one could attain three levels of degrees: the bachelor of arts, the master's, and the doctor's (from the Latin *docere* 'to teach'). The bachelor of arts degree entitled one to continue for a higher degree. The master's and doctor's were earned through the defense of a thesis, demonstrating one's scholarship. The curriculum for the bachelor's degree remained the seven liberal arts. Because of a continued lack of books in the Medieval period, the method of instruction was still by lecture, delivered by either a master's or doctor's candidate who read something he had written and provided commentary. There was no minimum age for attending the university, and it was not unusual for students to be as young as 12 years old.

As in earlier times, a thorough knowledge of Latin was essential for the successful completion of studies at the bachelor's level and a prerequisite for more advanced study. By this point in time, however, Latin was no longer any student's first language. So, to ensure that students would acquire proficiency in Latin, not only for conducting research and writing but also as a means of spoken communication, students were required to use Latin as all times, in and out of class, even in the 'colleges' (student residences): "It has been decreed that the speaking of Latin shall be strictly observed in all the colleges and lodgings, not only by the simple students but also by the bachelors, according to the statutes, . . . on penalty of a certain fine to be imposed" (Seybolt, 1921: 72). Students were encouraged to report their peers who didn't speak Latin outside of class. In fact, some students were appointed language spies, called 'wolves,' who recorded the names of students who used the vernacular (their native language) instead of Latin. The

students whose names appeared on the lists were summoned and fined.

For conventional and religious purposes during the Medieval Age, Latin remained the language of school even as it became further and further removed from students' linguistic reality outside the classroom. Students did not possess a functional command of Latin; it was a not used by the vast majority of people in the wider community. Latin was a foreign language. Most students did not use it readily and had to be forced to speak it.

Revival of Classical Studies

With the rediscovery of classical authors, there was a renewed enthusiasm for the *studia humanitatis*; that is, the classical Latin education including literature and history. The proponents of the new learning, the humanists, advocated more than just the correction of manuscripts: They proposed a revival of classical learning and culture. They sought to institute Latin as the language of wider communication, much the way that English is used today. The school curriculum, then, continued to be devoted to the liberal arts, but with the insistence that texts of the ancient authors form the content of the curriculum. Students would, once again, learn language in conjunction with content, through exposure to excellent models, and not as a system of abstract rules. The most prominent educators of the day – Vittorino da Feltre, Guarino Guarini, Desiderius Erasmus – exhorted that learning should be pleasant, that harsh discipline was unnecessary and counterproductive, and that errors are artifacts of a developing grammatical system and not a sign of linguistic or moral decay. New attention was paid to the surroundings and comfort of the pupils, as evidenced by Vittorino da Feltre's delightful boarding school, the *Casa Giocosa* (the Playful House), where children learned Latin and Greek in an Italian countryside villa while enjoying fresh air, simply prepared food, and lots of physical exercise and outdoor games. Erasmus, the Dutch humanist, not one to mince words, put it boldly when he wrote in his treatise *On the right method of instruction*,

> I have no patience with the stupidity of the average teacher of grammar who wastes precious years in hammering rules into children's heads. For it is not by learning rules that we acquire the power of speaking a language, but by daily intercourse with those accustomed to express themselves with exactness and refinement, and by the copious reading of the best authors" (Woodward, 1921: 163–164).

Rise of the Vernacular Languages

The humanists' best efforts notwithstanding, they failed in their quest to establish Latin as the universal language. A combination of economic, religious, political, and scientific developments worked against them. As nations formed across the European continent, national languages solidified national identities. Increasing criticism of the abusive power of the Catholic Church stigmatized the use of Latin by association. Although Latin prevailed for a while longer as the language of scholarship and international relationships, it began to lose ground as the vernacular languages grew increasingly powerful. Scientific discoveries began to be published in the vernacular. Galileo published his treatise on planetary movements in Italian, not Latin. The rise of a middle class of merchants and bankers legitimized the vernaculars as media of communication. Parents needed to be convinced of the value of having their children devote so much time and effort to learning Latin. Perhaps the event that had the most significant effect on the language teaching was one of the greatest inventions of all time: the printing press, which allowed for the mass production of books. For the first time, students had easy and relatively inexpensive access to texts. They no longer needed to commit everything to memory or to laboriously copy reams of commentary and lecture notes. Moreover, it wasn't long before the Latin texts were readily available in translation, either interlinear or in side-by-side columns. Such innovation had the obvious effect of eliminating the need for students to struggle through the Latin text to understand its meaning. They could simply read it in their native language.

In addition to his condemnation of the excesses of the Catholic Church, Martin Luther was also a proponent of widespread literacy education. He advocated free elementary education for all children in Germany so that they would be able to read the Bible and thereby attain salvation. Philip Melanchthon functioned as Luther's mouthpiece for educational reform. On the basis of his observations in schools, Melanchthon proposed a three-level system. The plan remained basically humanist, with the innovation that children should first be taught (level 1) in the vernacular before proceeding to the Latin grammar school (level 2) and the conventional course of study, followed by the university (level 3). The rules and regulations that Melanchthon outlined, however, suggest anything but a golden age for learning: those for the university students prohibit a long list of weapons that students were not to bring to their classes, along

with curfews for evenings in the pubs and recommendations to students on how to organize their time effectively.

In England, Sir Thomas Elyot authored the first book on education written and printed in English language, the *Boke named the Governour* (1531). While still advocating the learning of Latin, he argued that English could be used just as well as Latin for scholarly purposes. The Spanish scholar and humanist Juan Luis Vivès (1492–1540) held that language is a living entity, not a static one, and that its use defines its grammar. He proposed that Latin should also be treated as a living language and not simply in imitation of Cicero. Vivès also advocated the use of the vernacular in teaching boys, even though he wrote his treatise in Latin. However, Pietro Bembo (1470–1547), in Italy, not only urged the use of the vernacular but wrote in Italian to praise the Italian language. Bembo was instrumental in establishing as the literary standard the Florentine dialect found in the literary masterpieces by Dante, Petrarch, and Boccaccio.

The Jesuits

The Catholic Church responded to its critics by calling the Council of Trent (1555) to initiate reforms from within. Its program (the Counter Reformation) depended on the education of clergy and laity. Ignatius of Loyola (1491–1556) founded the Society of Jesus, the Jesuits, using a military model: Members would be soldiers who fought for the cause of religion. The Jesuit system of education, although criticized for its elitism, has enjoyed tremendous prestige and esteem since its founding in 1540. The graduate of a Jesuit school was expected to think clearly and logically, express himself eloquently and effectively in speech and in writing, and possess erudition. The *Ratio studiorum* ('Plan of Studies') was the Jesuits' exhaustive description of their educational model. Again, it was a liberal arts curriculum, based on and devoted to the study of Latin. In the lower grammar school, students spent almost 25 hours per week on the study of Latin. Ignatius himself advocated the learning of Latin through literary texts, with Latin as both the medium and the content of instruction. Students were admonished to use Latin at all times. The use of the vernacular was strictly limited, allowed only for the purpose of learning to deliver sermons in it when necessary. Extensive teacher training, rigorous organization, and a carefully prescribed curriculum were hallmarks of the Jesuit system. Despite a lengthy and highly supervised period of training, the least prestigious position was held by the teacher of grammar.

Toward the Modern Era

The esteem with which the Jesuit system was held provided impetus for the Protestants to design a educational system that could compete with it. In opposition to the elitist nature of the Jesuits, the educational reforms proposed by Johannes Comenius included public education for all, regardless of aptitude or intelligence: "a sieve, if you continually pour water through it, grows cleaner and cleaner, although it cannot retain liquid" (Comenius, 1657: 67). A renewed emphasis on observation, experimentation, and reasoning within the scientific paradigm of the day was realized in Comenius's curriculum by a focus on direct experience and learning through the senses. He advocated that pupils study things before words and that teachers organize materials into a natural order, by presenting ideas incrementally, beginning with the known and gradually introducing the unknown, and by recycling material at increasing levels of complexity throughout the curriculum (what he referred to as "the concentric method"). He was also strongly in favor of repetition, explicit error correction, and accuracy from the very beginning: "the first attempt at imitation should be as accurate as possible, that not the smallest deviation form the model be made. . . . For whatever comes first is, as it were, the foundation of that which follows. If the foundation be firm, a solid edifice can be constructed upon it, but it be weak this is impossible" (Comenius, 1657: 199–200). Although his treatise, *The Great Didactic* (1657) contains many contradictory statements, Comenius's textbooks were his claim to international fame. His major contribution to education is his pioneering use of illustrations as an integral, not merely decorative, element in language textbooks. He, too, advocated elementary instruction in the vernacular school, followed by the Latin school.

Even the most ardent proponents of vernacular education, although advocating education for all, restricted it to the elementary level. Thus they ensured rudimentary vernacular literacy and religious education for the common people. Secondary schools (gymnasia, grammar schools, lycée, academies) were still based on the Latin model and remained the intellectual territory of the elite: boys from well-to-do families who could afford to sent them off to school to be trained in the liberal arts.

Vernacular education at the elementary level predominated in the 17th and 18th centuries, whereas the commonest type of secondary school remained the traditional Latin school. The 'naturalistic' movement in education reflected the major philosophical points of Romanticism and naturalism; namely, an emphasis on emotion as opposed to reason, an intense

interest in nature and intuition, and the belief that the closer man remains to his natural state, the more authentic he is. Rousseau (1712–1778) authored a treatise on education in novel form, *Èmile*, in which he proposed that man is by nature good, but becomes spoiled by the restraints of society and formal education. This position was in direct opposition to the notion that man is born evil and must be saved by God's grace. In line with his philosophical position, Rousseau recommended the elimination of schools altogether.

Êmile, however, influenced the ideas of Johann Basedow (1723–1790) in Germany, who established an experimental laboratory school, the *Philanthropium*. His methodology abolished rote memorization, advocating instead the use of games and a natural, immersion-type approach to teach language, even Latin: "They [the youngsters] played the 'Command' game. You see, it is this way: first, they all stand in a row like soldiers, and Herr Wolke [the teacher] is the officer who commands in Latin, and they must do everything he orders. For instance, when he says *claudite oculos*, they close their eyes tightly: or, *circumspicite*, they peer around in all directions" (Cole, 1965: 429–430) Basedow's curriculum emphasized the importance of the vernacular as the language of instruction and led, ultimately, to the elimination of the Latin grammar schools.

The Lesson of Tradition

When the connection between language and content was severed, Latin became a subject in the curriculum, like science or music, rather than its foundation. Moreover, as it no longer functioned as a means of communication – other than to read ancient texts that were readily available in translation – it served no utilitarian purpose and so could be abandoned for the sake of including more practical subjects in the curriculum. The learning of language for a practical purpose presupposes certain social and economic conditions; for example, international politics, evangelization, commerce, travel, and globalization. In the 20th century, 'living' modern languages replaced Latin in the curriculum, but interestingly, although the language changed, the teaching methodology did not. The legacy that the teaching of Latin left on the early–20th-century curriculum was one of a system of abstract grammatical rules and translation, despite centuries of reformers' advice to the contrary.

In an attempt to create successful classroom conditions for language learning, educators returned, perhaps unknowingly, to the last, most confident era of language teaching – the ideal method – in the tradition of Comenius and the Jesuits. Many methods were introduced: The Silent Way, Suggestopedia, Community Language Learning, and the Berlitz Method. Audiolingualism, a language teaching method popular in the United States in the 1960s, promised to produce competent second-language users through the use of pattern practice, with lots of repetition and absolute accuracy from the beginning. The presentation of language was so rigorously prescribed that learners were not allowed to make mistakes or form bad habits. Touted as a 'scientific' method–based partially on principles of behaviorism in psychology – it prompted schools to make huge investments in language learning laboratories, where students donned headphones, listening and repeating what they heard on tapes. Needless to say, the method did not produce the results it had promised. Unfortunately, it did produce a generation of learners who were convinced that they were incapable of learning language and a cadre of school administrators who were reluctant to invest in future language learning schemes.

The communicative language teaching movement that became popular in the 1970s emerged in opposition to the grammar translation practice of teaching Latin, behaviorist approaches, and any rigidly prescribed method. Proponents of the approach argue that learners acquire language through the interpretation, expression, and negotiation of meaning, rather than through the study of grammatical rules, translation, or mimicry. Others propose immersion education or content-based instruction to maintain the connection between language and content, in a way similar to the bilingual system in early Rome. Others seek to recover the humanist tradition and the centrality of literature in language teaching. Those who take a fully vocational approach suggest curricula designed to teach Language for Special Purposes. Rhetoric and argumentation have resurfaced in Language for Academic Purposes courses.

Consonant with a society that values scientific over humanistic endeavors, some applied linguists look for a scientific orientation to language learning. Such approaches place a renewed emphasis on providing learners with models, in the form of 'input.' Research continues to investigate the extent to which earlier is better, especially with regard to the acquisition of native-like pronunciation. Other linguists take a more philosophical approach and seek to discover universal truths about language and its acquisition, fueling the debate about whether language derives from innate faculties of the human mind or environmental factors.

Language teachers, having never heard of Quintilian, Jerome, or Vittorino da Feltre, readily embrace the role of affect in language learning to explain why

it is important to create an environment that is conducive to learning. They consult language teaching manuals that suggest the use of concrete objects, body movements, and illustrations to convey meaning and to support language development. They include authentic texts in the curriculum to provide models of real language use, although the glossing of text may take the form of hyperlinked text, rather than interlinear translation.

Whether, when, and how to deal with learner's errors remains a concern, as well as how to focus learners' attention on form, without losing sight of meaning. How much and what kind of grammar instruction might enhance learning is still under discussion.

Language teaching tradition reveals that true innovations may be rare, but when confronted with the necessity of implementing instruction that leads to successful language learning, the voice of tradition still echoes in contemporary practice.

Introduction

The essence of language is communicative activity occasioned by human contact. While social groups remained small and mobile, speech was the most effective medium through which communication could take place, and the acquisition of spoken language became a 'natural' feature of infant development with similar mental processes available for later reuse if required. Five or six thousand years ago, however, human history took a new turn with the emergence of large and permanent settlements in the great river civilizations of the ancient world including Mesopotamia, Egypt, and northern China. In these and similar instances the imposition of social discipline on large populations entailed the creation of durable sign systems to buttress the ephemeral convenience of speech. Visible symbols were etched, painted, or otherwise inscribed on stone, clay, and other long-lasting substances to create permanent texts from epics to inventories. But writing is not a 'natural' process which can be acquired through contact. It has to be taught and learned.

The writing skills trained in the early scribal schools moved beyond their immediate utilitarian function of recording and preserving factual

information in lists and other records. New traditions of text creation grew up giving some of the languages or dialects in which they were written a special 'classical' status, which endured long after the communities which spoke them had died out, making them languages that had to be taught and learned consciously rather than acquired through personal spoken contact. The first of these classical languages was Sumerian, which, like Latin at a later date, was assimilated into neighboring cultures where the need for a prestigious literary language could not be met locally. In other cases, however, languages developed classical varieties of their own by preserving highly valued texts and protecting the language in which they were written from the effects of change wrought by colloquial speech. In the process, they created diglossic situations maintained through educational practices for centuries. Classical Chinese is a well-known example, so also are Sanskrit in India, and Arabic which, since the 7th century C.E., as the classical language of the Koranic texts has coexisted with a growing number of local varieties of colloquial Arabic in the Middle East and North Africa. Such classical varieties can of course be 'spoken' in the sense of consciously 'performed,' and like Latin they may even form the basis for a lingua franca, but they lack native speakers and therefore have to be taught to each new generation, often as a rite of passage into an educated elite.

By contrast, the teaching of 'ordinary' foreign languages for utilitarian purposes was not considered a proper use of expensive resources when they could be 'picked up' through direct contact. In Europe, for instance, Latin was the only language admitted to schools and universities for well over a millennium after it ceased to be a living tongue. It was not until the spread of printing technology after the mid-15th century that any serious demand for a reading knowledge of vernacular languages grew up along with the grammars, dictionaries, and other devices through which they could be taught and learned. Despite this increase in status, the teaching of so-called 'modern' languages did not find easy acceptance in the schools – in part because of opposition by the classicists, but also because it was not easy to find permanent teachers (most were peripatetic native speakers, i.e., temporarily resident foreigners).

Not until the 19th century did modern 'contact technologies' start to emerge which totally transformed the system of world communication and hence the teaching of languages. First was the expansion of steam-driven transport headed by railways that enabled an unprecedented number of speakers of different languages to meet face-to-face, and steamships that clamped the bonds of centralized European control ever more tightly on a growing number of colonial territories around the planet. Next came telecommunications which performed much the same functions without anyone having to move from their offices and culminated in 1901 with Marconi sending his first Morse-coded radio message ('SOS') from England to Newfoundland. More were to follow, the technologies of sound recording (1877 onward) being particularly important in the present context, until the new age of the microcomputer which *inter alia* offers facilities that have to some extent redressed the balance in favor of writing (e-mail, fax, etc.) and raised again the possibility of instant translation.

Utilitarian principles of education have become the norm and with them a reasonably secure place for the teaching of foreign languages. However, the emergence of a 'world community' on the back of mass air transport has increased the demand for a small number of 'superlanguages' with a global status, led by English. The future of many smaller languages has become increasingly precarious, but whether they can be saved through deliberate teaching–learning strategies without a growing native-speaker base is doubtful.

The Ancient World

As noted above, the first instance of organized language instruction in history was the training given in the scribal schools of the ancient world, starting in the cities of Sumer (southern Mesopotamia) and Egypt about 5000 years ago. In neither case was literacy widely distributed among the population at large; it was seen as a specific set of skills shared by qualified craftsmen who had been specially trained for the job. Scribal training was long and demanding (it included the preparation of writing materials for instance), but it was much sought after, and scribes belonged to an envied elite, a few of whom graduated to powerful positions in administrative or priestly castes.

Their geographic proximity suggests that the (slightly) earlier Sumerian work may have influenced the Egyptians. The two systems had some similarities, but technology was not one of them: Sumerian signs were incised with a wedge-shaped ('cuneiform') stylus into tablets of soft clay which were allowed to harden, whereas the Egyptian hieroglyphs and their cursive variants were inscribed on flat surfaces such as papyrus with a brush (later a pen). However, as communication systems they both started by devising pictographic images to represent words whose referents were easy to draw such as *man, woman, tree, sun*, etc. (rather like modern foreign language textbooks). These were later supplemented by more abstract ideographic symbols, but there came a point

when pictures of any kind were impossible (in writing proper names, for instance), and, more generally, there was the crucial problem of inventing new signs. A set of systematic procedures was needed that could generate a readable sign from any spoken word.

At this point, Sumerian and Egyptian diverged; in the former, syllables played an important phonological role whereas the latter was a Semitic language in which words could be written down without specifying the vowels because they were predictable from their consonantal context. Despite its linguistic inappropriacy, Sumerian cuneiform was adapted for use by neighboring Semitic languages about 2500 B.C.E., rendering the system even more difficult to teach and learn. At the same time, the prestige of Sumerian as the original written language turned it into the world's first classical language with a literature, mainly of religious texts, which was studied in the Near East for about a thousand years after the spoken language died out.

The influence of the Egyptian system was even more significant than cuneiform. It was adapted for use by other Semitic languages in the area, and in the case of at least one variant used by the Phoenicians and others living in what is present-day Lebanon the signs came to represent individual consonants rather than sequences, thus creating the first alphabet. The consequent lightening of the learning load was a crucial factor in the success of its subsequent dissemination, including in particular its adoption by the Greeks some time between 1000 and 800 B.C.E. (See British Museum (1990) for articles on above topics.)

At the other end of the learning scale from alphabets are logographic orthographies consisting of large numbers of distinctive signs ('characters'), each representing an individual word. The most famous example is Chinese, the world's longest surviving writing system, which has been in continuous use since the second millennium B.C.E. Despite its drawbacks, it is still intact and regarded as a defining feature of Chinese identity. One reason for this longevity is linguistic: logographic characters suit a key feature of Chinese, namely the dominance of monosyllabic words with no internal structure. The second and more important reason is cultural. In its classical form, the written language came to provide a unifying force in Chinese national life which helped to counteract the disunity of a large number of increasingly diverse spoken dialects. Classical Chinese grew from the decision to maintain the language used in the texts of Confucius (551–479 B.C.E.) as emblematic of a high written culture sustained by a formidable system of competitive written examinations which controlled entry into the rarified circles of imperial administration. The classical language retained its power in this way until the foundation of the Republic in 1911 when moves were made to replace it with a new standard based on the northern (Beijing) dialect known since the 1949 revolution as *putonghuà* ('common language'). A new alphabetic orthography called *pinyin* has had only limited success, however, since its introduction in the 1950s.

Literacy did not make much progress in the ancient world, possibly because the early nonalphabetic systems were too difficult for most people to learn, encouraging the growth of exclusive scribal monopolies that came to exercise considerable political and religious control. As an everyday skill, it was undoubtedly useful for listing, labeling, and the like (Linear B, an early Greek orthography deciphered in the 1950s to much public acclaim, turned out to have been used for little else). There was also a demand from the rich and powerful for monumental inscriptions to commemorate triumphs of various kinds, but as far as most people were concerned, reading had little interest. Communication and fun were well enough supplied by spoken language – there was no need for a replacement.

The Classical World

Greece: c. 800–100 B.C.E.

Some time in the early centuries of the first millennium B.C.E., the Greeks made their second and successful attempt to acquire a system of writing by adapting the consonantal alphabet they saw being used by the Phoenician traders of the Levant. They immediately seized on the advantage of having a small number of signs to learn, but realized that for Greek they would need to represent vowels and they used otherwise superfluous Phoenician signs for this purpose.

Nobody knows exactly when or where this transaction took place, but it is generally agreed that by 800 B.C.E. the Greeks had an alphabet, and the relative ease with which it could be learned helped it to make an impact in different parts of the country. Greece did not suffer from the restrictive practices of an intolerant priestly caste or other forms of scribal protectionism (Goody, 1987). In fact, it was uniquely Greek that an early priority for the new technology should have been to provide a written version of the Homeric epics which were already familiar in their oral storytelling guise. The resulting text (completed about 700 B.C.E.) effectively defined Greek identity for the future and functioned as the indispensable foundation for a groundbreaking approach to education.

As Athens moved toward the democracy for which it was to be famous in the 5th century, a system of education was essential to prepare the future rulers

(i.e., all freeborn males) to participate fully as responsible citizens and to recognize that citizenship brought duties as well as privileges. If 'ordinary' men were to take part in the governance of the city and the dispensation of justice, the people had the right to expect from them a maturity of thought and expression made evident through the effective control of spoken language in the public arena.

The learning of eloquence began in the schools whose prime responsibility was the teaching of grammar, i.e., correct spoken and written Greek, to older children. Later, as young adults, they undertook advanced training in rhetoric and dialectic (the logical structure of argument), building up the three-part curriculum that, as the 'trivium,' was to underpin schooling in medieval Europe. This intellectual continuity also owed much to the writings of Aristotle (specifically on rhetoric and dialectic, for which he devised the syllogistic structure).

For the Greeks, learning grammar meant studying their own language (they rejected foreign languages as mere 'bar-bar' ('barbarian') noises), and it was not an analytic process of taking sentences to pieces. It was rather an investigation of the way language was used by writers of repute: 'grammar is the practical study of the normal usages of poets and prose writers' as Dionysius Thrax (c. 170–190 B.C.E.), a teacher of Greek as a foreign language in Alexandria, said in his *Tekhne grammatike* ('The art of grammar,' c. 100 B.C.E., Kemp, 1986: 346).

The basic pedagogical strategy was mimetic, i.e., the absorption by memorization of substantial amounts of text as the basis for the production of appropriately elevated discourse. The first task was, therefore, as Thrax put it, to develop 'skill in reading (aloud) with due attention to prosodic features' (Kemp, 1986), a priority which was less strange than it would be today (our preference for silent reading derives from medieval monasticism). But there was also a practical reason, namely the correct identification of words and longer syntactic units in texts which were written in *scriptura continua*, i.e., without word separation, (Coulmas, 1999: 455–456). Try, for example, the following English sentence; it should prove helpful to read it aloud using appropriate rhythm and intonation ('prosodic features'):

> 'onereasonformemorizationistobuildupapermanent-mentalstoreoftexts' (Coulmas, 1999: 25).

To make things even more difficult, Greek texts were sometimes written in lines running left-to-right and right-to-left alternately (so-called *boustrophedon*: lit. 'ox-turning').

Teaching grammar from texts rather than from rules ('inductively' rather than 'deductively,' to use more recent terms) reflected the lack of analytic grammars, a priority which needed to be revised when Alexander's acquisition of an empire in the Near East created a demand for Greek as a foreign language. Dionysius Thrax's *Tekhne grammatike,* already referred to above, contains an account of the famous eight 'parts of speech,' and it has been called the world's first pedagogical grammar, but there is some doubt about the historical status of this feature of the book (Kemp, 1986; Law and Sluiter, 1995/1998; Robins, 1997). With so many texts lost in whole or in part, all we know for sure is that the direction of change at this time was toward a greater concern for the teaching of linguistic form, and that this trend continued under the Romans for whom Greek was a second language which every educated Roman was expected to learn.

Rome: c. 100 B.C.E.–400 C.E.

By the time of Dionysius Thrax, the Romans were in full control of Greece itself and were moving to take over the entire Hellenistic world in the Near East (an aim consolidated by their victory over Cleopatra at Actium in 31 B.C.E.). In a gesture of tribute unprecedented among conquerors, the Romans adopted Greek culture as their own and consciously modeled themselves on their predecessors. As a result, education in Rome was a bilingual system in which precedence was given to the study of a foreign language, a pattern repeated later with Latin in Europe, but in a more extreme form. There was in consequence a demand for grammars of both languages, and many were produced though few have survived, and even fewer are complete.

In the present context, the most influential surviving document from the Roman period is the 12-volume *Institutio oratoria* ('Education of an orator') by Quintilian (Marcus Fabius Quintilianus, c. 35–100 C.E.), the leading rhetorician of his time. The book deals in detail with the making of an orator from early childhood onward. Concern for good language, Quintilian argued, began in the home and parents should take care to bring children up speaking Latin correctly and well. Learning Greek was the first major priority, though the time devoted to it should not be excessive. Acquiring it from a native speaker at home before starting school gave children a clear advantage, and educated Greek slaves were regularly purchased for this purpose, often with their freedom guaranteed when the family no longer needed their services.

Formal schooling, a privilege open only to boys, typically began about the age of seven. The first task was learning to read and write (Quintilian was insistent on the value of an elegant and well-practiced hand). Practice was also the key to accurate and fluent reading following the 'method of syllables,' i.e., 'sounding out' syllables of increasing length and building them into words, an approach which remained the norm in Europe until quite recent times. Once basic literacy skills had been acquired, the child (now aged about twelve) was ready to leave his so-called *literator* and enroll with a *grammaticus* who taught him Greek and Latin grammar.

The aims of language education in Rome followed the Greek example, namely the development of effective skills in public speaking based on the correct use of language strengthened by a detailed knowledge of the great writers. As with the Greeks, much of the training took the form of the memorization and recitation of substantial amounts of text. The main difference, however, was the need to learn Greek as a foreign language, a task which entailed the formal analysis of sentences, i.e., the eight 'parts of speech,' which are discussed in some detail in Quintilian I.

After leaving school, the young adult could continue his education with a *rhetor* such as Quintilian himself whose principal objective was to train him how to speak effectively in contexts such as the law courts or the Senate house (the Romans did not share the Greek interest in disputation, so dialectic was less popular). The teaching methods were based on the study of models (Cicero, etc.) followed by specially constructed improvisation exercises. All the emphasis was on simple but well-delivered rhetoric and the avoidance of self-indulgent oratorical ornamentation.

Among the few language teaching texts that have survived are portions of *De lingua latina* ('On the Latin language') written around 45 B.C.E. by Marcus Terentius Varro (116–27 B.C.E) and a pedagogical grammar of Greek from the 2nd century C.E. written by Apollonius Dyscolus. It has a syntactic slant which it seems influenced Priscian the great Latin grammarian of the 6th century (see below).

Eventually, just as the empire was about to collapse, there appeared what must be the most famous textbook in language teaching history: the two-volume *Ars grammatica* ('The art of grammar') by Aelius Donatus, a teacher of Latin in Rome about 350 C.E. (Law, 2003: 4.6). The first volume, the elementary *Ars minor* ('Shorter grammar'), became synonymous with 'teaching grammar' for more than a thousand years. It is short and discusses each of the eight 'parts of speech' in turn following a catechistical design ('What is a noun?' 'It is a part of speech which has case . . .' etc.) plus a few rather sparse examples. The more advanced *Ars maior* ('Longer grammar') also covers pronunciation and takes up specific problem issues. The question-and-answer format of the *minor* allowed the teacher to test ('hear') what had been learned in a systematic manner. A typical school classroom contained all the pupils regardless of level, which meant that they had to work on their own until summoned by the teacher who repeated the questions in the book. The consequences of error were usually unpleasant, and the best way of avoiding painful failure was by rote memorization, with or without understanding.

Donatus, it should be said, was the last representative of imperial Latin and by a curious coincidence he became the teacher of St Jerome (c. 342–420 C.E.) whose translation of the Bible (the so-called 'Vulgate') became the first major work in the patristic Latin which replaced it and came to dominate the educated culture of the Middle Ages.

The Medieval World

The adoption of Christianity as the official religion of the Roman Empire in the 4th century C.E. provided Western Europe with an intellectual coherence and a common language that sustained it during the waves of (often violent) change between 400 and 600 C.E. which swept the ancient world into history. Not only did Latin itself survive, albeit in a modified form suited to its new patristic role, but it spawned a set of vernacular dialects influenced by contributions from incomer languages such as Frankish. Only in the province of Britannia (which excluded the Celtic lands) was the imperial language replaced entirely by the speech of the Germanic tribes that over-ran it after the withdrawal of the legions. Although the influence of Latinate Rome returned eventually (596 C.E.), the linguistic 'distance' between Latin and both Celtic and Anglo-Saxon gave teachers from the British Isles (sometimes called 'insular' scholars) a special insight into many of the problems faced by elementary learners.

The history of language and education in the Middle Ages can be divided into three broadly defined phases. The first (c. 400–800 C.E.) was a postimperial period which, despite political instability, saw the establishment of a monastic system that gave the church a place of refuge and nurture for a variety of purposes including schooling. This process was complete by the time of Alcuin and Charlemagne in the late 8th century.

Phase two (800–1200 C.E.), between Charlemagne and the so-called '12th-century renaissance,' was notable for two developments. The first was the transition to a more secular society during which education

left the monasteries and began to put down roots in the towns and cities. The second was the growth of new professional studies, but always with Latin as the medium of instruction, which reinforced its unifying role across the continent. Eventually, specialist centers emerged, the so-called 'universities,' the first of which were founded in Bologna, Paris, and Oxford about 1200.

During the third phase (1200–1500), the universities (particularly Paris) encouraged a revival of interest in the ideas of Aristotle stimulated by new translations of his work into Latin. Their impact on linguistic studies focused on the relationship between language and the outside world, which was expressed through various 'modes' of meaning (*modi significandi*, see Law, 2003: chapter 8). Eventually, however, this excessively cerebral scholasticism provoked a new humanism which *inter alia* stimulated a more extensive use of vernacular languages, most controversially in the translation of the scriptures. It might have been expected that this passion for 'real life' would reduce the importance of Latin or even extinguish it altogether. However, the opposite happened: the medieval world disintegrated, but the Latin language rediscovered its classical roots and became the leading force for the study of (pagan) literature.

Phase 1: From Donatus to Alcuin (c. 400–800 C.E.)

At a time when the single most stable cultural feature of medieval Europe was the Latin language, learning it was both an achievement in itself and the gateway to further advancement (in fact, to be literate (*literatus*) meant to be able to read Latin).

We have already noted the appearance of Donatus's *Ars grammatica* about 350 C.E. The analytic approach it adopted underlined the shift of pedagogical priorities from literature to language which was characteristic of the postimperial approach to the teaching of Latin as a foreign language. A century and a half after Donatus, this trend was amplified in the work of Priscian, a teacher of Latin from North Africa who worked in Constantinople about 500 C.E. (see Law, 2003: 4.10). His students were mainly speakers of Greek, and their learning priorities were reflected in the design of his 18-volume study, *Institutiones grammaticae* ('the teaching of grammar'). Most of the work deals at length with accidence, but it ends with two books devoted to syntax. Initially, it was too detailed to gain widespread popularity, but, after winning the support of scholars during the so-called 'Carolingian renaissance' in the 8th century, it was accepted as a key work for advanced learners (McKitterick, 1994).

Grammar was not just a 'useful subject,' however. It was the foundation of the so-called 'liberal arts' curriculum which, as we have seen, had its roots in classical times but which was now systematized into a two-stage framework of seven subjects starting with the language-based 'trivium' (grammar, rhetoric, and dialectic) followed by the more advanced number-based 'quadrivium' (arithmetic, geometry, astronomy, and music). Apart from grammar and elementary arithmetic, most of these subjects were beyond the scope of the schools, but they eventually formed the basis for the work of the universities (12th century onward). The intellectual groundwork for the approach was laid by St Augustine about 400 C.E. and expanded by scholars such as Boethius (c. 475–524 C.E.), who devised the term 'quadrivium,' and Cassiodorus (c. 490 to c. 580 C.E.), an early leader of the monastic movement whose *Institutiones* (c. 550) set out the curriculum in some detail. A little later came St Isidore of Seville (560 to 636 C.E.) who devoted the first three books of his 20-volume *Etymologiae* to an account of the seven arts.

The culmination of this first phase of medieval language education came with the work of an Englishman, Alcuin of York (c. 737 to 804 C.E.). In 781, he was hired by Charlemagne as a special educational advisor and based in a monastery in Tours where he founded a school. Alcuin's writings covered all three subjects of the trivium (his work on grammar contributed to the renewed interest in Priscian, for instance), but like many in the early church he had a special interest in dialectic. Dialectical reasoning encouraged the exploration of links between logic and theology, for instance, whereas rhetoric was less relevant in an ecclesiastical context that favoured disputation, ritual, and prayer rather than extempore preaching.

Phase 2: Latin and the Vernacular Languages (800–1200 C.E.)

After the time of Charlemagne, there were two parallel linguistic processes at work which ultimately defined the scope of the school curriculum in early modern Europe. The first was the expansion and diversification of the role of Latin as education became part of a wider and more secular community. Schools for children were only one instance; there were also specialized centers for adult students which provided professional studies in subjects such as law, medicine, and administration. From the late 12th century onward, these centers formed loosely structured societies of teachers and students called 'universities' (*universitas societas*) which attracted customers from many different countries. Latin was therefore needed both as a medium of instruction across a broadening curriculum and as a spoken lingua franca in a polyglot community.

The second strand of change was the new maturity of the vernaculars, their defining moment being the appearance of major literary texts, some of which, like the Homeric epics of old, had their origins in oral storytelling. Among the earliest were *Beowulf* (Old English) and the *Chanson de Roland* (Old French), both committed to writing before 1000 C.E., and they were followed by works in other languages, culminating in Dante's *Divina Commedia* (1307–1321). But these were still early days: the vernaculars did not yet offer a serious educational alternative to Latin. There were, however, a few examples of Latin grammars written in the students' mother tongue, including one in Old English by Aelfric, Abbot of Eynsham (c. 955 to c. 1020) who also composed a bilingual glossary for learners, and a famous *Colloquium* (dialogue) with an interlinear translation to help the teacher (pupils did not normally possess personal copies of texts). For the most part the teaching of Latin followed the well-trodden paths of Donatus and Priscian, but there was an interesting pedagogical novelty in the shape of grammars in verse, including the widely used *Doctrinale* of Alexander of Villedieu (c. 1200).

So far as learning the vernaculars themselves was concerned, it was assumed that they would be acquired through spoken contact as and when they were needed, and any teaching would be informal. Eventually, a few self-study manuals (*manières de langage*, Lambley, 1920) started to appear, but most international travellers had to get by in some form of Latin or invent a private lingua franca of their own.

Phase 3: The Later Middle Ages (1200–1500)

Intellectual endeavor in the later Middle Ages took a special interest in exploring the relationship between rationality as represented in, for instance, the newly 'discovered' works of Aristotle and spirituality as manifest in Christian theology. The result was a complex system of categories which drew attention to links between ways of understanding (*modi intelligendi*) and means of expression (*modi significandi*). Important though the *modistae,* as they were called, were in higher educational circles, their work had little direct influence on the teaching of Latin except perhaps at a very advanced stage.

Eventually, however, the rarified atmosphere of modistic theory reinforced the view that the study of language had turned into a formalistic and abstract cul-de-sac. There was therefore an urgent need to replace the 'artificial' patristic Latin of the church with the 'genuine article' derived from the great classical authors, pagan though they may have been, and by the 14th century the search was on for copies of neglected texts, conducted by scholars such as Petrarch (1304–1374) and Boccaccio (1313–1375).

At the same time there was a growing interest in learning classical languages other than Latin, including both Greek and those of the Near East, Arabic and Hebrew. A major step forward was a beginners' book for Greek called *Erotemata* ('Questions') in a question-and-answer format based on Donatus (Law, 2003: 223–227). Later, Western teachers started to visit Constantinople in order to acquire Greek at first hand, and after the fall of the city to Islam in 1453, native speaker refugees fled to the West.

The pedagogical implications of these changes were far-reaching. Grammar remained the foundation discipline in the schools, but the shift away from the medieval concern with dialectic was accompanied by a broader, text-based interest in classical literature which reinstated the importance of rhetoric. Initially, change was slow, partly because of the familiar problems of textual copying, but, with the arrival of printing in the mid-15th century, texts of every kind started to circulate in increasing numbers, facilitating a range of choices which had not been available before.

The Early Modern World

So far as language teaching in schools is concerned, the early modern period brought little structural change until the late 18th century. Even in Protestant countries where the rejection of Latin represented a major change of church practice, it continued to dominate the school curriculum, with the occasional addition of Greek, and modern languages were ignored if not deliberately excluded. As we have seen, there were two major reasons for the survival of the classics, apart from inertia: first, there was the use of Latin in the universities, and second, the influence of Renaissance humanism which encouraged the reading of classical literature. In this connection we should note that the newly created printing industry freed the reading community from the editorial priorities of the scriptoria. By the 1550s, the output of classical literary texts had far outstripped that of formerly dominant religious works (Febvre and Martin, 1984: 264; Eisenstein, 1993).

Printing also facilitated the production of grammars and other works (dialogue manuals, glossaries, etc.) designed to help adult learners to cope with an increasingly polyglot world of 'national' languages. The most impressive was John Palsgrave's grammar of French, *Lesclarcissement de la langue francoyse* (1530), but there were many more modest contributions including James Bellot's *English Schoolmaster* (1580), the first manual expressly designed to teach

English as a second language. The customers were Huguenot refugees in London, some of whom opened schools to teach French to English children (Lambley, 1920; Howatt, 2004).

For most children, however, 'school' meant 'Latin,' and 'Latin' continued to mean 'grammar,' though in England there was at last a replacement for Donatus. Known informally as 'Lily' (after one of the authors) or the 'Royal Grammar' because its adoption was made mandatory by royal proclamation (1540), it was called *A short introduction of grammar* and consisted of an introductory account in English of the parts of speech (by John Colet) followed by a syntax in Latin (by William Lily). For more fortunate students, however, Latin instruction sometimes included the study of literary texts, and the best-known pedagogical account came from Roger Ascham (1515–1568) in his *Schoolmaster*, published posthumously in 1570. Ascham had moved in high royal circles and his book was designed for the education of the courtly elite who wanted to develop a good literary style and elegance of expression. It became famous for a teaching method known as 'double translation' in which the learner translated the Latin text into his mother tongue and, after carefully comparing the two texts, the original Latin one was removed and he had to recreate it from his English translation. An important feature of this technique was the insight it provided into the workings of the mother tongue at a time when the formal study of the vernacular was unknown.

Life for the average early modern grammar school pupil (aged between 8 and 14) was as dreary and painful as it had ever been: nothing but the memorization of grammar rules with no sign of humanism in any sense of the term. '[I had] miserably lost the sweetest spring-time of life … on scholastic trifles,' complained the great educationist Jan Amos Comenius (1590–1670) in 1636 in his *Great Didactic* (Sadler, 1969: 6). This sentiment was echoed later in the century (1693) by John Locke (1632–1704) who described the child as 'chained to an oar, seven, eight or ten of the best years of his life to get a language or two [which could] be learnt almost in playing' (*Some thoughts concerning education,* 1693, cf. Axtell, 1968: 254).

Both men suggested radical reforms which had some impact among more enlightened teachers. Comenius for instance attempted to construct a graded set of textbooks designed to provide a coherent curriculum suited to the growing child (taking him 'from the known to the unknown'), but the only text to find much success was his famous illustrated book for beginners called *Orbis Pictus* (1658). Locke suggested a 'natural' approach to teaching foreign languages, including Latin, by conversational methods ('talking it into children'), but his proposals were really aimed at well-to-do families who could afford to hire private tutors rather than use the moribund grammar school system. In the second half of the century, advanced educational opinion influenced by Jean-Jacques Rousseau's *Emile* (1762) even called for the abolition of *all* language teaching to preadolescent children (including mother-tongue literacy), claiming that it encouraged a form of empty verbalism which caused positive harm by obstructing the child's direct experience of the natural world. These ideas were too extreme for Enlightenment Europe, but they proved attractive to more romantic 19th-century reformers such as Pestalozzi (1746–1827) and Froebel (1782–1852).

Outside the schools printing transformed the fortunes of the vernacular languages in at least two fundamental ways apart from the obvious expansion of the number and range of available texts, (see Eisenstein, 1993). First of all it encouraged the processes of standardization, which were already in progress for sociocultural reasons, making it possible eventually for the vernaculars to be taught alongside (or instead of) Latin in school. Spelling was the obvious first target, but the process spread to all aspects of language. Some of the major European languages, e.g., French and Italian, were taken over by national 'academies' which issued directives on grammatical correctness and stylistic propriety. Others such as English avoided this fate but developed a standardized form through public support for 'authoritative' texts, including Samuel Johnson's *Dictionary of the English language* (1755), Robert Lowth's anonymous *Short introduction to English grammar* (1762), and John Walker's *Critical pronouncing dictionary* (1791).

Second, there was an increased interest in learning foreign languages, particularly for reading purposes. Initially, grammars of minority languages such as English were in Latin (e.g., John Wallis (1653) and Christopher Cooper (1685), both called *Grammatica linguae anglicanae*), but locally produced bilingual works grew in number during the 18th century. Because there were few teachers of modern languages (they all taught Latin), there was a market for 'compendious' self-study manuals which contained everything: a grammar, including guidance on spelling and pronunciation, dialogues and reading texts, glossaries, practical tourist information, and so on. The need for examples of spoken language (dialogues such as 'at the inn,' etc.) stemmed from an expansion of international travel which had become safer by 1750, if not more comfortable, and increasing numbers, mainly of wealthy Britons, set out on the so-called Grand Tour to Italy by way of France. Because

the Tour could take months or even years to complete, learning a modicum of French and/or Italian was essential.

Working through a language manual was possible for well-educated gentlemen who were familiar with grammar from school, but it was too demanding for most children who needed a graded course of instruction. Eventually, in 1783, J. V. Meidinger published *Praktische französische Grammatik* to teach French to speakers of German. It offered a new method which was much better suited to beginners: the grammar was divided into digestible amounts and presented in a step-by-step fashion along with short bilingual lists of new words. In addition, there were exercises consisting of sentences to translate into and out of the foreign language. This design, which eventually became the norm both for school textbooks and adult self-study manuals, is known to us as the 'grammar-translation method,' but this was a label invented by its detractors in the late 19th century. Modern languages were ready at last to enter the world's classrooms.

The 19th Century

As noted in the Introduction, the 19th century was a period of technological innovation with far-reaching consequences for international communications (transport, mail, telegraph, telephone, etc.) and so for the teaching and learning of languages. Adult learners adjusted to the new situation, but it took a long time for the practicalities of real life to have any serious impact on secondary school language classrooms which continued to be dominated by grammar, literature, and 'the exams.'

Within Europe, for instance, mobility on the railways increased the likelihood of face-to-face contact with foreign language communities and hence a growing need to learn how to speak their languages. Outside Europe, there were two main developments. The first was the growth of European colonialism which tightened its stranglehold with the development of fast modern steamships. In the British Empire (outside India which was a special case), there were attempts by the colonial authorities to provide a limited amount of organized schooling on the model of elementary education at home.

English was normally the medium of instruction but attempts to teach it 'as a foreign language' were out of the question. The only model was the grammar-translation method, and there were no grammars or dictionaries. Schooling began with 'Reading' and 'Writing' and not 'English,' which was a fourth-year subject that included 'parts of speech' and 'literature' just as it did in London. Schools were also run by missionary societies, particularly after the end of the infamous slave trade, and many broke new ground by providing orthographies for their pupils' mother tongues in order to prepare materials for the teaching of reading, but they did little else.

Second, there was a steady increase in the importance of the United States, particularly later in the century when it became the destination for large-scale emigration, which created new needs for English, both among those who went to America and those who stayed behind but wanted to visit their families. As a new immigrant from Germany himself, Maximilian Berlitz (1852–1921) was among the first to realize that such students needed completely different teaching methods to help them to speak a foreign language, and he founded his first language school in Providence, Rhode Island, in 1878 to meet this need.

The 19th century was also a time of intellectual exploration, with a new interest in applying the aims and methods of the sciences to the study of human affairs including language and its history. The science of phonetics was an early manifestation of this interest, and its impact on language teaching from c. 1880 onward was considerable.

Despite all these new needs and opportunities in the outside world, formal education took little notice. New moves in elementary education created improved levels of literacy, but there was no role for languages other than the mother tongue. Foreign languages were for the elite only, and Latin, despite losing its utilitarian role in the universities, maintained its position as a high-prestige subject with massive snob appeal. Modern languages by contrast had to fight for recognition, and the only way they could achieve this was by aping the classics and teaching grammar, translation, and worthy literature. It was not until the last two decades of the century that anybody took the spoken language seriously.

The Grammar–Translation Method

As we saw above, the so-called 'grammar–translation method' had been developed by Meidinger with school pupils in mind, and his approach was widely imitated, e.g., by J. G. C. Fick (1763–1821) who wrote the first course in English for speakers of German in 1793, and by Karl Ploetz (1819–1881), the best-known language textbook writer in continental Europe. By the mid-1800s grammar–translation had become the standard secondary-school method for both modern and classical languages, and it was particularly well-suited to the priorities of written examinations. It was also adopted by the growing adult market which developed a new 'series' approach to textbook publishing. An author devised a 'template'

(which he called his 'method') and then adapted it to an unlimited number of different languages. The best-known examples were Franz Ahn (1796–1865) whose 'new, practical, and easy' method first appeared in 1834, and, a year later, the even more famous H. G. Ollendorff (1803–1865) who promised to teach a new language in six months. Their customers were for the most part self-improving adults often with a practical need for a foreign language, but schoolteachers regarded the books as 'too easy,' and they strongly disapproved of making 'keys' available to check the exercises.

When the grammar–translation method started, it lived up to its aim of simplifying language teaching by presenting one or two new grammar rules plus a short vocabulary list in each lesson and following them with translation exercises ('exercises' were a novel development).

Unfortunately, the simplicity of the early courses was not maintained as the century wore on. The impact of exams with their 'unseen' translations packed with tricky linguistic minutiae encouraged teachers to include 'everything' in case it 'turned up,' and the textbooks followed suit. The reputation of the method was seriously damaged as the grammar rules became more complex, the lists of 'exceptions' longer, the vocabulary more esoteric, and the exercises sillier, e.g., 'The pen of my aunt is in the garden of the Dutchman' (parodied over many years).

Inadequacies of this kind prompted many individuals to put forward new ideas for reform (see Howatt, 2004: chapter 13 and Howatt and Smith, 2000). Among the best-known were Claude Marcel's (1793–1876) proposal for a 'reading first' approach in *Language as a means of mental culture* (1853) and an interesting but rather limited suggestion by François Gouin (1831–1896) that language lessons should be organized around a 'series,' i.e., a piece of sequential behavior such as opening the window (*L'art d'enseigner et d'étudier les langues* ('The art of teaching and studying languages') (1880). None of these 'bright ideas' made much headway. What was needed was a new methodology which was well-grounded in theory and sensible in practice, and one appeared in the form of the so-called Reform Movement (see Howatt and Smith, 2002).

The Reform of Language Teaching

The key feature of the Reform Movement, which began in the early 1880s, was the historic decision to give spoken language educational precedence over literature. Signs of change began to appear as phonetics gained greater acceptance in the academic world and younger language teachers saw it as a practical starting-point for pedagogical reform. This early link with linguistics was fostered by leaders of the Movement across Europe. In Germany, for instance, there was Wilhelm Viëtor (1850–1918) whose pseudonymous pamphlet *Der Sprachunterricht muss umkehren!* ('Language teaching must change direction completely!') started the ball rolling in 1882, in Denmark Otto Jespersen (1860–1943) who provided the best account of the classroom implications of the Movement in *How to teach a foreign language* (1904), in France Paul Passy (1859–1940) one of the founders of the International Phonetic Association (a lasting monument to the success of the Movement), and in Britain, Henry Sweet (1845–1912) whose *Practical Study of Languages* (1899) became an applied linguistic classic.

The reformers also insisted on two further classroom principles: the use of sensible connected texts (no more silly sentences), and the 'inductive' teaching of grammar by drawing it out of a close study of the texts. In addition, bilingual words lists were rejected, and translation, particularly into the foreign language, was to be avoided as far as possible. It is important to realize that the Movement appealed to secondary-school teachers, i.e., nonnative speakers of the languages they were teaching, but phonetics provided the help they needed to put speech first.

The translation issue came to dominate a similar but less academic new approach called the 'direct method,' which was popularized, but not invented, by Maximilian Berlitz in his schools in America and later in Europe (see Howatt and Smith, 2000: V). The Berlitz schools were intended mainly for adults with limited practical needs. They set out to develop a conversational approach which was enhanced by the presence of a native speaker teacher who did not know the students' mother tongue, and if he did, he was required to deny it. The 'don't translate' motto became the trademark of the method and virtually all the classwork was oral. If there was a theory behind this, it was a rather simplified version of the view that acquiring a second language was essentially the same as acquiring the first – hence the need for conversation, the absence of grammar and translation, and a delayed start to reading and writing.

The 20th Century

During the 20th century, education around the world was transformed, and language teaching along with it, as schooling in basic literacy became universal in principle if not always in fact. More generally, education ceased to be preoccupied with the grooming of an elite and shifted permanently to a utilitarian philosophy in which the curriculum was judged in terms

of its relevance to the perceived and potential needs of the whole community. The classics were largely replaced in school by major foreign or second languages and, given the structure of the world order that emerged after 1945, it was inevitable that English would become the first choice in many if not all instances. The following account inevitably reflects this bias.

The Growth of English Language Teaching (ELT)

As the language of the British Empire, English had spread around the globe in the previous three centuries, but in colonial schools it was still perceived as a 'quasimother tongue,' and until the 1920s teachers used methods and materials originally designed for elementary schools in the United Kingdom. Provision, never generous, was supplemented by missionary schools of various denominations which devoted their energies to teaching literacy in the local mother tongues. In Europe by contrast, English had taken its place in the secondary schools as a foreign language alongside French and/or German, and it had been at the cutting edge of the 'applied linguistic' reforms initiated by the Reform Movement, particularly in the teaching of pronunciation. It was, however, only in the adult sector that the purely utilitarian objectives of Berlitz and his imitators were followed in direct-method conversation classes.

These two strands of 'reform' and the 'direct method' came together in the work of Harold E. Palmer (1877–1949) who taught English along Berlitz lines in Belgium from 1902 until the German invasion in 1914. He was then forced to return to London where he renewed an earlier contact with Daniel Jones (1881–1967) who had since become the head of the Phonetics Department at London University and was about to publish his famous *English pronouncing dictionary* (1917). The two worked together for nearly seven years (1915–22), during which time Palmer published a series of books, including *The scientific study and teaching of languages* (1917) and *The principles of language-study* (1921), which established a new approach to practical language pedagogy called the Oral Method, combining his classroom experience with the insights of modern phonetics (see Smith, 2003: II).

After 1918, a significant straw in the postwar wind was the decision of the Japanese government to reform English teaching in order to promote greater spoken fluency. They approached Palmer who accepted a position as a special advisor starting in 1922. The following year he was appointed as the Director of an Institute for Research in English Teaching (IRET) (1923–1936), where through both research and materials development, he helped to create a specialized profession which came to be known as 'English language teaching' (ELT) after the founding of a journal of that name in 1946 under the editorship of a close Tokyo colleague, A. S. Hornby (see Howatt, 2004).

A second interwar development was the emergence of 'English as a second language' (later, ESL) to refer to educational contexts (initially colonial) where the language played a significant role in the learner's environment. The phrase was first used in a research project in Bengal (modern Bangladesh) in the early 1920s which investigated the notion that reading was a more useful teaching objective than speaking in countries such as India. The key argument in the project report (1926) by the director Michael West (1888–1973) was that education should be bilingual, i.e., the mother tongue should come first, but an international language such as English had a useful 'secondary' role to play, particularly in science and technology. This view grew in influence and after decolonization in the 1950s and 1960s it became the norm in countries where English was retained alongside the national language(s). 'Second language' was also used in 'English-speaking countries' such as the United States, the United Kingdom, etc., to characterize the role of English among members of minority language communities.

West's report also contained practical suggestions for teaching materials that stressed the importance of vocabulary control, extending a research theme that was also present in the work of Palmer and others in Britain and America. In 1936, the investigation culminated in a so-called 'general service list' of the 2000 most useful words for reading materials in ELT (not published until 1953). There was also an ambitious attempt by C. K. Ogden (1889–1957) to create an 'alternative language' called Basic English (1930) by using only 850 words of ordinary English. It made a useful contribution to wartime teaching, but its long-term appeal was limited (see Howatt, 2004; Smith, 2003: V).

The third and final thread in the development of ELT was the rising demand for English as a foreign language (EFL) in the United Kingdom itself during the 1930s, mainly from refugees from war-threatened Europe. After 1945, there was a pause until the1960s when TEFL began to grow fast.

Out of these influences postwar ELT developed a recognizable approach of its own which stressed the importance of carefully graded texts containing the new grammar patterns, a limited vocabulary of frequent items and an oral method which presented the new items in 'situations' that made the meaning clear without having to translate too much. It was

assumed that, with minor modifications, the same course could be used successfully by all learners. In this it was influenced by ideas in linguistics and psychology (see below), which came to be called 'applied linguistics' in the United States in 1948. When these disciplines changed direction in the 1960s, language teaching followed suit.

Language Teaching and Applied Linguistics

In the Reform Movement we saw the first attempt to apply ideas from the new linguistic and behavioral sciences, a trend that continued to grow as the academic study of these subjects took root, particularly in the United States where a strong theoretical foundation was laid down between the wars. The chief linguistic characteristic was the collection and description of data, particularly of Amerindian languages, while psychology focused on basic learning processes such as habit formation. Together they created a 'structural' tradition that had a direct impact on language teaching during and after World War II.

In 1943, for instance, the United States launched a large project called the Army Specialized Training Program (ASTP, see Angiolillo, 1947) to train spoken foreign language skills. Following the new ideas, they created a drill-based methodology designed to habitualize linguistic structures, or 'speech patterns.' When adapted into mainstream language teaching by Charles C. Fries (1887–1967) at the English Language Institute at Michigan, it became known as the Oral, later Structural, Approach (Fries, 1945). The term 'applied linguistics' was coined in 1948 and with it classroom techniques such as 'pattern practice,' which were well-suited to the technology of the language laboratory, that became popular in the early 1960s. With the new technology 'structural' methods became known as 'audiolingual.'

During the 1960s, applied linguistics shifted its attention from 'microlinguistic' matters such as identifying phonological and grammatical patterns to a broader concern with the way language is acquired and how it is used in social contexts. Language acquisition was a key issue with the generativist school of linguistics associated in particular with the work of Noam Chomsky from 1957 onward and in particular his controversial claim that human beings are innately endowed with the capacity to acquire language, the obvious question in the present context being whether this process can work more than once. By the 1980s, there was a substantial body of theory and research into 'second language acquisition' (SLA), which influenced language teaching by emphasizing the importance of natural language use in, for instance, comprehension (Krashen, 1985) and problem solving (Prabhu, 1987). The latter proved influential in stimulating interest in 'task-based learning' in the 1990s.

Alongside psycholinguistics grew the development of sociolinguistics which aimed to account systematically for language variation, in particular the relationship between the standard (written) language as taught in the schools and the dialectal variability of everyday speech in the outside community. This concern was reflected in a shift in foreign language pedagogy away from formal linguistic patterning to the functional uses of language in everyday social life. Out of this grew the dominant teaching methodology of the late 20th century: 'communicative language teaching.'

Communicative Language Teaching (CLT)

The starting point for CLT is the use of language in communication – who uses it, how, when, etc. – and the way that these variables are reflected in the linguistic choices people make when they talk, write, etc. An influential contribution to the early discussion of this issue was a series of lectures by the philosopher J. L. Austin (1911–1960) published as *How to do things with words* (1962) in which he proposed that utterances should be regarded as 'speech acts' (suggestions, requests, questions, etc.) which controlled the development of social discourse. When these new functional categories were added to more traditional semantic notions (location, duration, etc.) in the 'notional–functional approach,' they provided an extra dimension to language teaching which was generally welcomed (Wilkins, 1976).

The best-known instance of CLT in this framework was an international project called the Threshold Level funded by the Council of Europe (1971 onward). The aim was to define the functional minimum competence that a learner should have, and to allow for cross-linguistic comparisons ('how do you make a request in English/ French/ Spanish . . . ?' etc.). Beyond the 'threshold,' however, learners had specific personal purposes for their learning which needed a rather different pedagogical approach.

Teaching English, and other languages, for specific purposes (ESP) was the second major strand in CLT, (Widdowson, 1978). Many adult students had pressing linguistic needs in their jobs, university studies, businesses, holidays, etc., and the communicative approach offered techniques for providing course materials and teaching programs. These included: authentic texts for reading and listening comprehension, activities to practice language in use rather than linguistic form, role-play and improvisation to provide experience of spoken interaction, and the

detailed study of specific genres and text-types suited to particular professional interests. 'Team teaching' linking subject specialists and language teachers was another common feature of ESP.

Conclusion

The growing dominance of utilitarian objectives in foreign language teaching has been evident since the late 19th century and is unlikely to change in the foreseeable future. Meanwhile, more cultural aims remain the concern of a diminishing specialist minority. However, if computer-based technologies of instantaneous translation are successful, some of the demands of everyday communication could be devolved to gadgetry, which would allow broader educational purposes to play a more central role in the teaching of languages.

Language, Visual Cognition and Motor Action

Introduction

From the beginning of the cognitive revolution, thinking about cognition has been dominated by the computer metaphor of mind. Cognition is conceptualized in terms of software that stores, retrieves, and manipulates abstract, amodal, arbitrary symbols (e.g., Pylyshyn, 1984; Turing, 1950). In principle, this software can be instantiated in a number of media, such as the human brain or a computer system. The assumption that the 'software' of cognition could be studied independently of the 'hardware' has had a marked impact on the field. Whereas before the cognitive revolution systems of perception and action held a central place in explaining human behavior, after the cognitive revolution these systems became irrelevant to the study of cognition. If cognition could be implemented and studied on a computer, then the fact that humans have sense organs and effectors is unimportant.

This 'disembodied' conceptualization of cognition has recently come under fire in the constituent disciplines of cognitive science, such as artificial intelligence (e.g., Brooks, 1991; Pfeifer and Scheier, 2000), philosophy (Clark, 1997; Newton, 1996; Prinz, 2001), cognitive psychology (e.g., Barsalou, 1999; Glenberg, 1997), cognitive neuroscience (Damasio, 1999; Pulvermüller, 1999), and linguistics (Langacker, 1987; Talmy, 1988). Theoretical arguments and empirical data have been adduced suggesting that cognition is grounded in perception and action. According to this 'embodied' view, perception, action, and cognition are closely intertwined. Here, we consider the implications of this view for language processing.

The embodied view of cognition conceptualizes language comprehension as the mental simulation of the state of affairs that is being described. These simulations are thought to involve the reactivation of patterns of brain activation that were recorded during the comprehender's interaction with the world (Barsalou, 1999; Damasio, 1999). These experiential traces (Zwaan, 2004) are not abstract, amodal, and arbitrary mental representations but, rather, are sensorimotor in kind. There is an increasing amount of evidence for the use of sensorimotor representations in language processing. This evidence is reviewed below.

Perceptual Processes and Representations in Language Comprehension

Researchers in cognitive linguistics have long argued that linguistic meaning is rooted in perceptual processes (e.g., Lakoff, 1987; Langacker, 1987). Consider a sentence such as, 'The cord runs from my laptop to the cable modem.' This sentence conveys a visual scan path from the laptop to the modem. The alternative wording, 'The cord runs to the cable modem from my laptop' sounds odd because it conveys an interrupted scan path, followed by another one (see Langacker, 2005, for a discussion). Consider also the sentence, 'The book is on my desk in my office on the fourth floor of the Longmire building.' Several variants of this sentence can be constructed that are all equally grammatical. One example is, 'The book is in the Longmire building on the fourth floor in my office on my desk.' However, some variants are awkward. 'The book is in the Longmire building on my desk on the fourth floor in my office,' sounds awkward because it does not convey a linear zooming-in or zooming-out process.

Brain-imaging studies have provided evidence that the processing of words engages the cortical and subcortical structures that are active when the words' referents are perceived. When subjects name words referring to actions associated with objects, brain areas just anterior to areas active during motion perception are activated, and when words referring to colors are processed, sites just anterior to areas active during color perception are activated (see Martin and Chao, 2001, for a review). Also, negative emotion words engage the amygdala, which is active when negative emotions are being experienced (Isenberg *et al.*, 2000). This evidence is consistent with the idea that words activate memory traces of perceptual experiences regarding the words' referents.

Behavioral evidence has provided further evidence that language and perception are closely intertwined. Subjects tend to make horizontal eye movements when listening to narratives describing horizontal motion and vertical eye movements when listening to narratives describing vertical motion (Spivey and Geng, 2001). Readers routinely activate the shape and orientation of objects described in sentences (Stanfield and Zwaan, 2001; Zwaan *et al.*, 2002). For example, on reading 'He saw the egg in the carton,' people name a picture of a whole egg more quickly than they do a picture of a broken egg, whereas the reverse is true on reading 'He saw the egg in the frying pan.' There also is evidence that visual primes

affect subsequent language processing (Boroditksy, 2000) and that visual displays presented concurrently with linguistic input may create interference (Fincher-Kiefer, 2000).

To summarize, linguistic analyses, brain-imaging studies, and behavioral experiments all converge on the conclusion that there is a close connection between language and perceptual processes. The argument can be made that meaning arises in part out of the perceptual simulations of the referential situation rather than out of the manipulation of abstract, arbitrary, amodal symbols (Barsalou, 1999; Glenberg, 1997; Pecher and Zwaan, 2005; Zwaan, 2004). The qualification 'in part' is important, because meaning does not just arise out of the language-mediated activation of perceptual representations and processes. Consider the sentence, 'John pounded the nail into the wall.' If the embodied view is correct, understanding this sentence involves not only the visual representation of a horizontal nail (Stanfield and Zwaan, 2001) but also an activation of motor representations and processes involved in pounding nails. In other words, the hypothesis is that meaning arises out of the simulation of actions in addition to the simulation of perceptions.

Motor Representations and Processes in Language Processing

Evidence for the claim that motor representations play a role in language processing can be drawn from three main sources: behavioral studies on adult language comprehenders, neuroscience, and studies of language acquisition.

Klatzky, Pellegrino, McCloskey, and Doherty (1989) describe one of the earliest experiments to show a relationship between motor activity and language comprehension. In their experiments, participants were asked to strike poses, such as raising their arm to eye level and pinching their index finger and thumb together. When holding these poses, the participants responded to sentences such as, 'Aim a dart.' Klatzky *et al.* (1989) report that participants were faster to respond when the action described in the sentence was consonant with the posture they were currently holding. Glenberg and Kaschak (2002) provide further evidence for the role of motor activity in sentence processing. When reading sentences that described action toward the body (e.g., 'Sam gave you a pen') or away from the body (e.g., 'You gave Sam a pen'), participants were asked to decide if the sentences were sensible. Half of the time, a 'Yes' response required making an arm movement toward the body; the other half of the time, a 'Yes' response required making an arm movement away from the body. Participants were faster to respond when the action described in the sentence was consonant with the action required to make a response. Most important, the participants' direction of response interacted with the direction of the action in the sentence not only for concrete actions (e.g., giving someone a pen) but also for actions that are abstract or metaphorical (e.g., the metaphorical transfer of information in, 'John told you a story').

Additional support for the role of motor representations in language processing comes from work in neuroscience. Pulvermüller (1999) reviews a body of research showing that perceptual and motoric representations underlie the processing of words. For example, processing words denoting actions or instruments (e.g., a hammer) appears to engage neural regions known to be involved in the planning and execution of actions (Grafton *et al.*, 1997; Martin *et al.*, 1996).

That perceptual and motor traces are recruited to build mental simulations of the events described in the language is congruent with research in cognitive development (e.g., Piaget, 1954) and language acquisition (e.g., Landau and Gleitman, 1985; Goldberg, 1998). One of Piaget's seminal contributions to the field of cognitive development was the discovery that the abstract thinking (or, formal operations) of adult cognition has its roots in children's understanding of literal, concrete events. For example, children may learn about abstractions such as 'causation' by observing how movements of their body effects change in the external environment (Meltzoff and Moore, 1997). Concepts such as 'equality' may be learned via experiences such as counting the number of marbles placed in two bowls.

Studies of language acquisition (e.g., Bailey, 1997; Landau and Gleitman, 1985) suggest that children's early acquisition of verb meanings (and, their acquisition of subcategorization preferences for verbs) relies on knowledge of the action that the verb describes. The relationship between action and verb meaning likely arises because the verbs are produced and understood in the context of particular actions (e.g., 'give' is likely to be accompanied by an arm movement to transfer an object from one person to another). Once a child understands what it means to 'give' in terms of literal actions (e.g., extending one's arm to give an object to someone), they can begin to understand metaphorical actions (e.g., transfer of information, as in telling someone a story) in terms of those literal actions (see Glenberg and Kaschak, 2002, for a discussion). Thus, the use of perceptual and motoric information in language comprehension that has been detailed

in psychology and cognitive linguistics may be, in part, a vestige of the processes involved in cognitive development and language acquisition.

Limitations of the Current Research, and Future Directions

Although there are theoretical arguments and an increasing amount of evidence in support of an embodied view of language comprehension, there are major hurdles to be taken. We identify three areas in need of further development.

First, as yet there is no coherent theory that specifies how perceptual and motor processes are integrated during perception. A key factor to consider in this regard is perspective (MacWhinney, 2005). For example, when we read, 'John stirred his coffee,' do we simply activate a dynamic visual representation of the coffee and the cup, of the hand stirring it, or perhaps of both? This is a matter of overt and covert 'visual' attention. However, an equally important question is whether we take the perspective of John or that of an observer. In the first case, we also would activate the corresponding motor representations of stirring a fluid in a cup with a spoon. In the observer perspective, we also might activate motor representations – given that viewing actions activates areas in the premotor cortex that overlap with areas active during self-performed actions (Rizzolatti and Arbib, 1998) – but presumably in a less elaborate fashion. We may further ask whether other sensory experiences are triggered by the sentence, such as the smell, taste, and temperature of coffee. An important challenge will be to identify the role of linguistic cues in perspective activation. Another important challenge will be to examine how background knowledge influences perspective taking. Conceivably, comprehenders are more likely to adopt agentive or observer-like perspectives depending on the extent to which they can recruit relevant experiences for each.

A second area in which theoretical development and data are needed is in the treatment of abstract concepts. It has been hypothesized that our knowledge of abstract concepts, such as 'justice' and 'slander,' is grounded in perception and action by way of metaphorical extension (Lakoff, 1987). For example, it has been suggested that applying the adjective 'warm' to an abstract notion such as relationships is grounded in the physical experience of warmth a child feels when she is being held by a parent. However, it is doubtful that this is sufficient. People have many direct experiences with abstract concepts, such as 'justice,' and without these, the metaphor would have not-ing to map onto (Barsalou and Wiemer-Hastings, 2005). Instead, Barsalou and Wiemer-Hastings suggest that abstract and concrete concepts are similar in that both involve situational context, but that they differ in which elements of the situational context are activated.

A third area in which theory development and data are needed concerns the operation of sensorimotor representations in complex linguistic situations. Currently, evidence in support of the embodied position is drawn from studies of the processing of single words and sentences. This leads to a simple and straightforward view regarding how and when sensorimotor representations are used in language comprehension. This simple view is probably inadequate to account for the role of this information in naturally occurring contexts of language use, such as having conversations and arguments, or reading stories. It will be important to examine what happens to sensorimotor representations in language processing tasks that are more representative of the way that language is used in our daily lives.

In conclusion, there is mounting evidence that language comprehension is best understood from an embodied perspective rather than from a disembodied perspective. Sensorimotor representations are clearly active during language comprehension. These findings notwithstanding, several challenges lie ahead for theories of embodied language processing.

Language/Dialect Contact

Introduction

The emergence of sociolinguistic approaches to dialectology in the 1960s represented a sharp break with the traditions of the discipline. Previously, dialect studies had largely focused on the collection of the most conservative speech forms in the community – research attention was largely directed toward rural areas, toward older people, toward men, and toward those with socially and geographically restricted lifepaths (Chambers and Trudgill, 1998). The studies which followed deliberately shifted attention away from such conservative language users to consider the urban, the young as well as the old, women as well as men, different ethnic groups and people of differing social statuses – the classic case is Labov's (1966) research in New York. They demonstrated, to highlight just a few of the very important contributions of this new approach, the orderly heterogeneity of language variation, and methods enabling us to examine language change as it was actually happening, as well as to spot the locus of change in the

community. These early and groundbreaking studies, however, were based solely on the analysis of natives to those communities, excluding migrants who made up often large proportions of the population, particularly of urban centers. Labov, for example, excluded well over 50% of New York residents from his sample on the grounds of nonnativeness (see Kerswill, 1993, for a discussion of this). This was, however, common practice in social dialectological studies for at least the first 20 years of the discipline.

This nativeness issue is important for two reasons. First, one could perhaps question the validity of dialect descriptions that exclude nonnatives in highly mobile communities such as large metropolitan cities. Second, and perhaps more fundamentally, excluding nonnatives can mask the very origins of some linguistic changes that are underway in the community. Horvath (1985), for instance, who did *not* exclude Italians and Greeks from her study of the English of Australia's largest city, Sydney, found that it was indeed these groups that were leading certain linguistic changes affecting the whole city. Furthermore, Fox (2005), studying the English dialects of adolescents in Tower Hamlets, an 'East End' suburb of London and supposedly the home of its 'Cockney' dialect, found that a number of the linguistic changes underway in that part of London are being led by the now majority Bangladeshi immigrant community and are spreading to the speech of White (especially) male adolescents there. A failure to consider the recently arrived immigrant group and a concentration on 'native' White adolescents alone would have projected almost unexplainable patterns of variation which represent a very clear and quite sudden break from the 'Cockney' dialect that preceded in this part of London. It appears, then, as if urban sociolinguistics was still analyzing rather idealized, 'tidied up' communities, and that this began to be seen as problematic for an all-embracing conception of the way varieties were evolving, given the levels of mobility, contact, and social heterogeneity that were being (or had been) witnessed in many locales around the world.

Dialect Contact and Koineization

Peter Trudgill's (1986) book *Dialects in contact* provided the impetus not just for research on the outcomes of rather radical contact between different dialects (such as colonial migrations) but also for a reconfiguration and reanalysis of dialect change more generally in the light of speaker mobility. Trudgill's basic argument was that if (usually convergent) linguistic accommodation occurs between speakers of different dialects over a sustained period of time (as it would in contexts, for example, of colonialism, urbanization, and migration), the accommodated forms can gradually become permanent features of the speakers' dialects. When children acquire language in a context of widespread accommodation among the adult community (much of which, it has to be said, is not necessarily particularly successful or accurate or complete), they develop an L1 that comprises a collection of accommodated forms and continue the accommodation themselves, passing on the converged norms to their own children, who eventually crystallize a focused dialect in the originally highly diffuse and heterogeneous speech community. Trudgill began to address the following questions: Given the different proportions of dialects which went into the original mix, what sort of new dialect emerges from the contact? What processes work on the mixture of dialects in order to focus that new variety? What determines the outcome? Research on dialect contact over the past 30 years points to four main processes which, together, are labeled *koineization* (see also Siegel, 1985).

'Leveling' is the term used for the eradication of marked (socially or in its typological sense) or minority linguistic forms in the dialect melting pot that follows population movement and has been shown to be the dominant force accounting for the structures of new dialects. A number of studies have convincingly shown that forms which were brought by a majority of speakers almost always survive to form part of the structure of the new dialect. Andrea Sudbury's pioneering study of the English of the Falkland Islands (FIE) (2000), for example, showed dramatic degrees of leveling between the input stage (mostly varieties of English from southwest England and Scotland, but also from other parts of Southern England) and present-day FIE. Gone (or almost gone), for example, are: rhoticity, initial fricative devoicing, periphrastic *do,* the velar fricative /x/, the /w–ʍ/ distinction, Scottish vowel length, double modals, the distinctive southwestern pronoun system and so on (see Sudbury, 2000: 202–206 for more details).

Our ability, of course, to highlight leveling as a dominant koineization process relies quite crucially on us having detailed and explicit knowledge both of the structures of the dialects in the input and of the demographics of their users. Kuo's (2005) study of the development of Taiwanese Mandarin (TM) (Chinese, Mandarin), which has formed over the half century since the flight of Chinese Nationalists from the Mainland after the Chinese Civil War (1945–1949), reminds us of the importance of understanding who brought which dialects to the mix. The previous literature on TM had suggested strongly that this new variety was different from Standard Beijing

Mandarin because of the second language acquisition failures of the non-Mandarin speaking population of Taiwan (mostly speakers of Southern Min (Chinese, Min Nan)) who were forced to learn and speak Mandarin after the Nationalists arrived from the Mainland. They pointed to the fact, for example, that while Standard Beijing Mandarin had four retroflex consonants in its inventory, Southern Min had none, and so, when learning Mandarin, the Southern Min speakers merged the retroflexes with corresponding nonretroflex consonants, and diffused the nonretroflex consonants to the children of original mainlanders. Through a very careful analysis both of the structure of Chinese dialects in the middle of the 20th century, and census information on the regional origins of the migrant mainlander population, Kuo demonstrated that while retroflexes were common in central Beijing, they were rarely found elsewhere in China, and were in a tiny minority of the migrant population to Taiwan. She argued, therefore, that the lack of retroflexes in TM was a simple result of them not having been brought to Taiwan in sufficient numbers in the first place, and that the few that were brought were swiftly leveled away (see also Britain, 2001).

'Simplification' refers to the process that leads to the new dialect being more regular, having fewer categories (such as gender, case, honorifics) and, for example, fewer person/number inflections than the dialects in the original mix. It is neatly exemplified by the many new varieties of Hindi/Bhojpuri which developed as a result of the migration of indentured laborers from the Indian subcontinent to work on colonial plantations in, for example, Fiji, Mauritius, South Africa, Trinidad, and Guyana (e.g., Barz and Siegel, 1988). Gambhir (1981: 259), for example, compared the number-, gender- and person-sensitive present tense system in Indian varieties of Bhojpuri (with over two dozen morphemes) with that of Guyanese Bhojpuri which has just two.

'Interdialect' forms are variants which did not exist in the input varieties, but have developed as a result of the acquisition of imperfectly accommodated forms. Usually they are forms intermediate between two or more of the input variants. In the Fens of Eastern England – koineized as a result of in-migration of southeastern and northwestern dialect speakers following marshland reclamation from the 17th century onward – contact between southern [ʌ] and northern [ʊ] variants of the vowel in words such as 'cup' and 'bun' has resulted in the gradual emergence of an interdialectal, phonetically intermediate [ʏ] form (see Britain, 2002).

Following 'reallocation' more than one variant survives from the dialect mix, but each survivor is reassigned to serve new functions. Khamkhong (2004), investigating new dialect formation in Ban Khlong Sathon (BKS), a small settlement in northeastern Thailand that was established in the 1970s and attracted migrants from across the country, found that reallocation accounted for the distribution of the Thai negators *bor* and *mai*. *Mai* is the negator used in Central (and Standard) Thai (spoken to the west of BKS), and *bor* the form used in the Isan (Thai, Northeastern) dialect of Thai spoken to the north and east of BKS, and these forms were preserved by the original migrants. Khamkhong's analysis of the grandchildren of the original migrants, however, found both forms being used, but each reallocated according to topic, with *bor* being used most and when discussing informal everyday topics, and *mai* reserved for discussions about more formal topics, such as lessons at school, health issues, and the local council.

Three Contexts of Contact

For the remainder of this article I discuss three major contexts in which linguistic varieties come into contact – 'new dialect formation,' the consequence of the mixture of distinct dialects in new speech communities, such as in colonial contexts, or as a result of labor movements, New Town formation, land reclamation, or urbanization; 'second dialect acquisition,' the ability (or otherwise) of migrants to acquire a second dialect of their own language; and the 'geographical diffusion of linguistic innovations.' The literature to date has tended to treat these as three distinct areas of enquiry, but I will attempt here to demonstrate that, in fact, the outcomes of each show remarkable similarities because all three have dialect contact at their core.

New Dialect Formation

It is the development of new dialects following large scale population movements that has provoked most research in the dialect contact literature (see, for example, Gambhir, 1981; Trudgill, 1986, 2004; Barz and Siegel, 1988; Britain, 1997; Sudbury, 2000; Kerswill, 2002; Kuo, 2005) and from which the assessment of the likely outcomes of contact – leveling, simplification, interdialect formation, and reallocation – has been derived. More recently, researchers have been looking in more detail at the likely order in which these expected outcomes develop following mass migrations.

Perhaps the most detailed investigation of new dialect formation has come from research on the origins of New Zealand English (Trudgill, 2004). At the disposal of the researchers was a large set of recordings

made in the 1940s of mostly elderly New Zealanders who represented the first New Zealand-born generation of Anglophones following the mass migrations from Britain and Ireland in the mid–19th century. Trudgill proposed three stages by which a mixture of dialects, over time, crystallizes into a more focused, less diffuse variety.

Stage 1: Rudimentary Leveling This stage occurs, he claimed, among adults at the very earliest points of contact between the speakers in the mix – in the case of New Zealand English at the various "assembly points in the British Isles, on the long boat journey out, and early on in the new location" (2004: 89). An example of such leveling is the absence in the New Zealand recordings of the merger of /v/ and /w/ into /w/ (e.g., [wɪlɪdʒ] for 'village') that was a receding characteristic of some dialects of the south of England in the mid–19th century.

Stage 2: Extreme Variability Children born shortly after arrival in a new speech community (such as Anglophone New Zealand in the mid to late 19th century) are faced with the task of focusing an L1 without a clear target. Trudgill claimed that in such circumstances children draw more on their parents' and other adult varieties than is usually the case, and the consequence of this, in a dialect mixture situation, is that they often use new and unusual combinations of features that derive from a wide range of dialects, and they often differ from each other quite radically too (see Trudgill, 2004: 103–105, for some examples of individual combinations). He also provided evidence of ongoing leveling, this time of forms which survived the journey, but not in sufficient numbers to be transmitted to the next generation.

Stage 3: Focusing through Deterministic Leveling This is the final stage, the stage at which a new, stable, relatively uniform variety emerges. It is at this point, with many of the minor 'competitors' already leveled away at an earlier stage, that certain forms finally win out. Trudgill claimed that, in almost every case, majority or unmarked forms win, and, perhaps controversially, that prestige, stigma and identity play no role in that determination. It is also at this point that reallocation may take place.

Second Dialect Acquisition

A more recent concern in dialect contact studies has been the factors that shape the ability of migrants to acquire a second dialect of their own language (or languages, as we shall see below). In contexts such as these, a speaker's dialect enters into contact with those of their newly adopted community. A number of common threads have emerged from the small amount of research on this topic to date. First, as might be expected from the research on second language acquisition, age of arrival in the community is crucial. Both Chambers (1992), investigating the acquisition of the English of Oxfordshire in England by Canadian children, and Watts (2000), looking at the acquisition of Cheshire English by American children, found that, on the whole, the younger the child on arrival in the new community, the more successful the acquisition of the second dialect. By contrast, Foreman (2003: 264), examining the acquisition of Australian English by North American adults, found that "the majority of the subjects did not acquire any phonetic or phonological aspects of AusE to an auditorily noticeable extent." While it is true that some studies have found some adjustments by adults in such settings, overall the finding of an inverse relationship between age of arrival and ease of acquisition is quite robust.

Second, it has been found that migrants acquire the new lexicon more quickly than the new phonology. Chambers (1992: 680) found, for example, that the group of Canadian migrant children he studied acquired over 50% of the examined lexical forms (such as using 'trousers' instead of 'pants,' 'nappy' instead of 'diaper,' etc.), but only a quarter of the phonological forms studied in their first two years in the nonnative speech community. Further evidence for this pattern comes from work investigating the acquisition of a second dialect of a second language. Laurie Chou (1997) investigated the extent to which Taiwanese were able to shift from the American English they had been taught in Taiwan to British English when working in England. She found that after three years in England her 30 subjects had acquired, on average, 78% of the 'British' forms from the British/American lexical pairs she investigated, but had /r/ deletion (in words such as 'car,' 'port' etc.) in 64% of tokens (compared with 41% among a control group of Taiwanese in Taiwan – suggesting a deletion rate of just 23% after three years).

Third, Chambers provided convincing evidence that 'simple' rules (i.e., dependent on automatic exceptionless distinctions) are more quickly and successfully adopted by second dialect acquirers than 'complex' ones (i.e. distinctions with exceptions, variant forms, and/or abstract linguistic conditioning, phonological splits, new phonemes, etc.) (Chambers, 1992: 682). He compared the acquisition of a voiceless British English intersonorant /t/ (a simple, exceptionless change from a Canadian English voiced [d]) with that of the COT–CAUGHT split – a lexically-diffused, phonologically complex characteristic of southern British English. While one 9-year-old

Canadian child in Oxfordshire acquired both features over 90% of the time, older children acquired the former, simple rule on average in around 45% of possible places, but the latter complex rule on less than one occasion in ten. In an investigation of the acquisition of three such 'complex' rules of Kuwaiti Arabic (Arabic, Gulf Spoken) by Egyptians, Al-Dashti found that female Egyptians acquired the local Kuwaiti [j] form of the variable (dʒ) and the [g] form of (q) but were unsuccessful in acquiring the [ð] form of (ð) (Al-Dashti, 1998), suggesting that some 'complex' rules are harder to acquire than others. Kerswill (1996: 200) proposed a cline of acquisition difficulty from vocabulary at the 'easy to acquire' end to lexically unpredictable phonological rules at the 'difficult to acquire' end as a way of classifying linguistic constraints on acquisition in a more fine-grained way.

Another, perhaps obviously significant, factor in acquisition success has been length of exposure to the target dialect. Chambers (1992), Al-Dashti (1998), Watts (2000), and Foreman (2003), for example, all showed that longer exposure leads to more successful acquisition. Further research is required on other social factors that may influence the acquisition process. Al-Dashti (1998) found significant gender differences in acquisition, with, in both cases, women proving to be better acquirers than men. Foreman's (2003) study of Americans in Australia emphasized the role of social identity in acquisition rates, claiming that 'feeling Australian' and engaging in mostly Australian and few American social network ties contributed to acquisition success. And Phili (2003) demonstrated that, if there are strong motivations to retain affiliation with their original communities, speakers appear to be able to resist shifting at all to new linguistic norms. She investigated speakers from Famagusta in Cyprus who were forced to leave their homes following the Turkish invasion of the north of the island, and who subsequently settled well away from their town of origin in Limassol. She found few differences between the speech of the migrants, thirty years after leaving Famagusta, and that of people still living in villages within the Famagustan dialect area (but on the Greek side of the divide).

Studies both of adults and children acquiring second dialects have provided evidence of interdialect formation. Watts (2000) showed that a majority of the American children, faced with the Cheshire English [ʊ] realization of the vowel in words such as 'cup' and 'mug' produced a vowel that was phonetically halfway between it and an American English [ʌ].

Evidence from the rather small second dialect acquisition literature also suggests, therefore, that contact processes are at work – 'simple' as opposed to 'complex' forms survive, suggesting leveling and simplification, with adult accommodation being less successful and complete than child accommodation, and occasionally instances of interdialect forms emerging.

The Geographical Diffusion of Linguistic Innovations

The spread of new linguistic variants from one place to another appears to operate in one of three different ways.

Wave-Model Diffusion Perhaps the most iconic model of the geographical spread of innovations and the simplest, since it depends solely on the friction of distance, is the 'wave' or contagion diffusion model whereby innovations, over time, radiate out from a central point, reaching nearby locations before those more distant. Trudgill, for example, in a discussion of the diffusion of changes from London to East Anglia in England, suggests that the slow, unsalient, and phonetically gradual diffusion of fronter realizations of /ʌ/ ('cup' [kʋp – kạp]) is spreading in a wave-like way (1986: 51–53).

Urban Hierarchy Diffusion A much more common finding is an urban hierarchical effect, with innovations descending down a hierarchy of metropolis to city to town to village. One such example is highlighted by Kerswill's (2003: 235–236) investigations of the diffusion of labiodental variants of /θ ð/ in Britain. He showed that [f v], having diffused, he claims, from London, have reached the cities of Bristol, Derby, and Norwich *before* the nearer but smaller towns of Romsey and Wisbech (see also Chambers and Trudgill, 1998; Hernández Campoy, 2003). The usual explanation for the hierarchical model is that, while the distance between the diffusing center and the receiving location plays some role, interaction between urban centers in modern societies is likely to be greater and, therefore, a more frequent and effective conduit for the transmission of new forms than between urban and rural. Transportation networks tend to link urban with urban, and economic and consumption infrastructures tend to be based in and oriented toward urban centers, with the ensuing consequences for employment, commuting, and leisure patterns, and these feed the hierarchical nature of diffusion.

In research on the vocalization of /l/ in Australian English, Horvath and Horvath (1997) showed that a combination of the contagion and urban hierarchy models can help explain the diffusion of some changes. They found, quite unexpectedly, that rather

than being most prevalent in the larger cities of Sydney and Melbourne, /l/ vocalization was most vigorous in "the most slowly growing parts of the older core" (1997: 120) of the country, the South Australian centers of Adelaide and Mount Gambier. They propose a 'cultural hearth model' whereby an innovation gains a foothold in both town and country in one particular region before diffusing to other regions.

Contrahierarchical Diffusion Only very occasionally, innovations diffuse against the urban hierarchy. Trudgill (1986) described how a number of smoothing processes found in rural north Norfolk in eastern England were diffusing southward to urban centers in the county of Suffolk. Hence, 'power' was undergoing change from /pɑuə/ to /pɑ:/, 'do it' from /dʉ:əʔ/ to /dɜ:ʔ/ and 'sure' from /ʃʉ:ə/ to /ʃɜ:/, etc.

The literature to date has not, broadly speaking, fully taken on board the consequences of seeing innovation diffusion as dialect contact – the contest between an incoming form and a local form – nor fully appreciated the problems with the approaches sociolinguists currently adopt with respect to diffusion, approaches which were abandoned in the human geographic literature over a quarter of a century ago (see Gregory, 1985, and for a sociolinguistic consideration of his arguments, Britain, 2002, 2005). Much of the literature, for example, assumes that, in diffusing spatially, the innovative form totally levels away the formerly used variants in its path, and that nonadoption of the innovation is a "passive state where the friction of distance applies a brake to innovation" (Gregory, 1985: 319). Furthermore, sociolinguistic models have concentrated on how the innovation spatially spreads almost to the exclusion of examining:

1. what happens to the innovation en route (Are the linguistic constraints on the use of the variant the same? Is the innovation evaluated in the same way in its heartland as it is in its new destination?); or
2. the social embedding of its promoters and receivers; or
3. the structural incongruities of the innovation and the traditional form it is attempting to eradicate.

In an investigation of the success (or otherwise) of a number of innovations spreading from London and the South-East of England to the Fens in the northwest of East Anglia, I showed (Britain, 2005) that, while some new forms were spreading successfully (all of which are notably less 'marked' than the forms they were replacing – e.g., the vocalization of /l/, the labiodentalization of prevocalic /r/, the fronting of /θ ð/ to [f v]), other 'innovations' were resisted (e.g., the fronting of /ʌ/). Furthermore, yet other innovations were only partly adopted, with the outcomes of the contact between old and new demonstrating reallocation or interdialect formation. In the East of the Fens, for example, the fronting of /ou/ (common in many dialects of English around the world) was only found in a historically defined subset of relevant lexical items – those deriving from Middle English **ou** (e.g., 'rows,' 'grown,' 'mown') – and was much less advanced in those words deriving from ME **o:** (e.g., 'rose,' 'groan,' 'moan'). How long this resistance to the innovation will last is questionable, but nevertheless the study shows that diffusion can lead to outcomes other than surrender by the local form (see also Trudgill, 1986; Britain, 2002). Hence we can see that innovation diffusion can be conceptualized in terms of the processes typical of contact – when an innovation meets a local form, koineization can occur (the mixture of variants tends to be 'resolved' in some way), and the outcomes can be leveling (one form wins over another) or reallocation/interdialect formation.

Basic Concepts

Let f: $\mathbb{N} \rightarrow \mathbb{N}$ be a function from natural numbers to natural numbers. Informally, an algorithm $\mathcal{A}$ has (time) complexity f if, given any input of size n, $\mathcal{A}$ will terminate after at most $f(n)$ steps. The subject of Complexity Theory is the mathematical study of the complexity of algorithms. This article explains the rudiments of Complexity Theory and outlines its application to the analysis of natural language.

Our first task is to make precise the concepts of 'algorithm,' 'size,' and 'step' mentioned in the previous paragraph. In the strictest sense, an *algorithm* is a deterministic Turing machine. Recall in this context that a *Turing machine* over a (finite) alphabet Σ comprises an infinite *tape* divided into discrete cells (or *squares*), a *head* that scans this tape one square at a time, and a finite table of *instructions*. Each instruction directs the head to write a symbol of Σ to the scanned square and then to move left or right, conditional on the current contents of the square and the current *machine state*. The number of possible machine states is finite, and the current machine state is updated, as each instruction is processed, according

to that instruction. Computation proceeds as long as some instruction can be executed; if a point is reached where no instruction can be executed, computation terminates. A Turing machine is *deterministic* if, at any point in its computation, exactly one instruction may be executed. Thus, for a deterministic Turing machine $\mathcal{A}$, the entire course of the computation is determined by the string of symbols initially written on the tape.

If Σ is a finite alphabet of symbols, it is customary to denote the set of finite strings over Σ by Σ^*. Let $\mathcal{A}$ be a deterministic Turing machine over some finite alphabet Σ; we say that $\mathcal{A}$ *computes* the partial function F: $\Sigma^* \to \Sigma^*$ defined as follows: if $w \in \Sigma^*$ is written on the tape and the Turing machine run, then $F(w)$ is the string left on the tape when the computation terminates. (We take $F(w)$ to be undefined if the computation does not terminate.) The *size* of an input string w is simply its length and the *steps* of computation are simply the basic instructions as specified in $\mathcal{A}$'s instruction table. Thus, we can make precise the informal definition of algorithmic complexity with which we started: a deterministic Turing Machine $\mathcal{A}$ has time complexity f if, given any input string of size n, $\mathcal{A}$ will terminate after at most $f(n)$ steps. Of course, $\mathcal{A}$ will not in general take the same number of steps for all inputs of size n; the function $f(n)$ is thus an *upper bound* on running time. This kind of complexity measure – known as *worst-case* complexity – is the most common measure employed in Complexity Theory.

In measuring the complexity of an algorithm, our primary concern is with *asymptotic* behavior. Thus, it is considered significant whether an algorithm has complexity n^2 or 2^n, or even whether it is has complexity n^2 or n^3, but not whether it has complexity n^2 or $300\,n^2$. The motivation here is that linear factors can always be mitigated by running the algorithm on faster hardware. For this reason, the following terminology has become current. For any function, f: $\mathbb{N} \to \mathbb{N}$, we write $O(f(n))$ for the set of functions

$$\{t : \mathbb{N} \to \mathbb{N} \mid \exists\, c, m \in \mathbb{N} \textit{ such that } \forall n > m, t(n) \leq cf(n)\}.$$

That is, $O(f(n))$ is the set of functions from natural numbers to natural numbers that are eventually dominated by some fixed multiple of f. An algorithm $\mathcal{A}$ is then said to have (time) complexity $O(f(n))$ if it has (time) complexity t for some $t \in O(f(n))$. Beware: this an *asymptotic* measure. If one algorithm $\mathcal{A}$ has complexity $O(n^2)$, and another algorithm $\mathcal{A}'$ complexity $O(2^n)$, that does ***not*** mean that $\mathcal{A}$ need run faster than $\mathcal{A}'$ in practice; it merely means that, if the size of the inputs can increase without limit, a point will be reached at which $\mathcal{A}'$ takes longer than $\mathcal{A}$.

Thus far, we have discussed the complexity of *algorithms*, but often what is of interest is the complexity of the *functions* that those algorithms compute. And this notion too can be reconstructed using the apparatus introduced above. Let Σ be a finite alphabet, let F: $\Sigma^* \to \Sigma^*$ be a function from strings over Σ to strings over Σ, and let f: $\mathbb{N} \to \mathbb{N}$ be a function from natural numbers to natural numbers. Then we say that F has (time) complexity $O(f)$ if there exists a deterministic Turing machine $\mathcal{A}$ computing F such that $\mathcal{A}$ has time complexity $O(f)$. More generally, if $\boldsymbol{f}$ is a set of functions from natural numbers to natural numbers, we say that F is in $(\boldsymbol{f})$-**TIME** if there exists a Turing machine $\mathcal{A}$ computing F that terminates in a number of steps bounded by some function in $\boldsymbol{f}$. Consider, for instance, the set

$$\mathbf{P} = \{p(n) \mid p(n) \text{ a polynomial}\},$$

giving us the complexity class **PTIME**. To say that a function F is in **PTIME** – or simply, 'is polynomial' – is to say that it can be computed by a deterministic Turing machine guaranteed to halt in a number of steps bounded by some polynomial function of the size of the input. Other salient sets of functions are

$$\mathbf{EXP} = \left\{2^{p(n)} | p(n) \text{ a polynomial}\right\}$$
$$\mathbf{2\text{-}EXP} = \left\{2^{2^{p(n)}} | p(n) \text{ a polynomial}\right\},$$

and so on. These give us, respectively, the computational complexity classes **EXPTIME**, **2-EXPTIME**, and so on. The union of the complexity classes K-**EXPTIME** for all $K \in \mathbb{N}$ is called the class of *elementary* functions. Functions F lying outside this class are called *nonelementary*. Finally, we note that, for a given function F: $\Sigma^* \to \Sigma^*$, it is not necessarily the case that there ***is*** a Turing machine that computes F at all. Such functions are said to be *noncomputable*.

Of particular interest in Complexity Theory are functions F: $\Sigma^* \to \{0,1\}$. Such functions are known as *decision problems*. (The intuition is that $F(w) = 1$ represents the answer 'yes' for a given input w, and $F(w) = 0$ represents the answer 'no'.) The following important notions relate specifically to decision problems. Let $\mathcal{A}$ be a Turing machine (not necessarily deterministic) and F: $\Sigma^* \to \{0,1\}$ a decision problem. We say that $\mathcal{A}$ *nondeterministically computes* F if, for all input strings $w \in \Sigma^*$, we have $F(w) = 1$ if and only if there exists a run of $\mathcal{A}$ that terminates with 1 written on the tape. Finally, let $\boldsymbol{f}$ be a set of functions from natural numbers to natural numbers. We say that the decision problem F is in the class $\mathbf{N}(\boldsymbol{f})$-**TIME** if F is nondeterministically computed by a Turing machine that terminates in time bounded by a function in $\boldsymbol{f}$.

As with the deterministic case, an important special case is the set **P**, giving us the complexity class **NPTIME** (or simply **NP**, as it is traditionally called). Similarly, we have the complexity classes **NEXPTIME**, **2-NEXPTIME**, and so on. Note the asymmetry in the definition of nondeterministic computation: if $F(w) = 1$, then a Turing machine nondeterministically computing F must have at least one run on input w terminating with output 1; if $F(w) = 0$, by contrast, no such run exists. For this reason, we sometimes need to speak about the complementary complexity classes **Co-NP**, **Co-NEXPTIME** etc.; a decision problem F is said to be in the class **Co-NP** if the decision problem F defined by $\overline{F}(n) = 1 - F(n)$ is in **NP**, and so on.

Just as we can count the *steps* involved in a run of some Turing machine, so too can we count the number of *tape squares* that it accesses. Again, we typically specify an upper bound on this number as a function of the size of the input. These complexity measures lead to classes **PSPACE**, **EXPSPACE**, etc., defined analogously as for **PTIME**, **EXPTIME**, etc. It is not necessary to talk about nondeterministic space-complexity classes, since they can be shown to coincide with their deterministic counterparts. In fact, the complexity classes mentioned above satisfy the inclusions:

$$\begin{aligned}\textbf{PTIME} \subseteq \textbf{NP} \subseteq \textbf{PSPACE} \subseteq \textbf{EXPTIME} \subseteq \\ \textbf{NEXPTIME} \subseteq \textbf{EXPSPACE} \subseteq \\ \textbf{2-EXPTIME} \subseteq \ldots \quad (1)\end{aligned}$$

The inclusions **PTIME** $\subset$ **EXPTIME** $\subset$ **2-EXPTIME** ... are strict: there are problems in **EXPTIME** that are not in **PTIME**, problems in **2-EXPTIME** that are not in **EXPTIME**, and so on. Whether the other inclusions in (1) are strict is a fundamental unsolved problem.

There is one final topic to cover before we apply these ideas to natural language. Suppose that F and F' are decision problems, with the following property: there is a function r: $\Sigma^* \to \Sigma^*$, which can be computed in polynomial time, such that, for all strings w, $F(r(w)) = F'(w)$. In such a case, we say that F' is (polynomially) *reducible to F*. If F' is (polynomially) reducible to F, any method for solving the problem F automatically yields a method for solving the problem F': first apply the function r to translate any given instance of F' to a corresponding instance of F and then apply the method for solving F. The time taken to solve F' in this way is no greater than the time taken to solve F' plus some polynomially bounded number of steps for the translation. Suppose now that it is possible to establish a result of the following form concerning a decision problem F: for all problems F' in some complexity class, F' is polynomially reducible to F. We then say that F is **hard** for the complexity class in question. Thus, for example, a problem to which any problem in the class **NP** can be polynomially reduced is said to be **NP**-hard, and so on. Intuitively, a decision problem is hard for a complexity class if it is at least as difficult to solve as any problem in that complexity class. Of particular interest are those problems that are simultaneously in some complexity class and hard for that class. Such problems are said to be *complete* for the class in question. Thus, problems can be **NP**-complete, **PSPACE**-complete, **EXPTIME**-complete, etc.

The theoretical framework presented thus far has employed the standard – though somewhat austere – view of an algorithm as a Turing machine operating on strings of symbols taken from a finite alphabet. In practice, however, when analyzing the complexity of a specific algorithm or function, a more relaxed concept of algorithm and a richer collection of data types are employed. There is no one 'correct' notion of basic operation here, but the fundamental principle is that basic operations should be executable in an amount of time that is, for the purposes at hand, bounded by a constant. Thus, for example, in problems where all the integers encountered are likely to remain small, it may be reasonable to regard the addition of two integers as a basic operation, since doing so gives a good estimate of actual running time. Similar remarks apply to measuring the size of the various data structures constituting the inputs of an algorithm.

Sometimes, the size of an input is best represented by more than one parameter, especially if that input is a tuple of data structures. The O-notation introduced above is extended to cover this case in the obvious way. For example, let f: $\mathbb{N}^2 \to \mathbb{N}$ be a function from pairs of natural numbers to natural numbers. We write $O(f(m,n))$ for the set of functions

$$\{t : \mathbb{N}^2 \to |\exists c, l \in \mathbb{N} \text{ such that } \forall n, m > l, t(m,n) \leq cf(m,n)\}.$$

An algorithm is then said to have (time) complexity $O(f(m,n))$ if its running time for any input of size m, n is bounded by some function $t(m,n) \in O(f(m,n))$.

For a comprehensive introduction to Turing machines and Complexity Theory, we recommend Papadimitriou (1994).

Recognizing Sentences

Let us see how the ideas sketched in the previous section can be applied to problems in linguistics. We begin with the recognition problem for context-free

grammars. Formally, a *context-free grammar* (CFG) is a quadruple $G = \langle N, V, S, P \rangle$, where N is a set of *nonterminals* (typically, category labels such as S, NP, VP, etc.), V is a set of terminals (typically, words such as *every*, *boy*, *loves*, etc.), S is a distinguished *start symbol* in N (for example, the category S) and P is a list of *productions* for rewriting nonterminals (such as, S → NP VP, NP → Det N, etc.). A CFG *accepts* the string of terminals w if some sequence of productions can be found that rewrites the start symbol S to w. (For a detailed discussion, see, e.g., Hopcroft and Ullman, 1979: 77 ff.) The *language of G*, denoted $L(G)$, is the set of strings accepted by G. The recognition problem for CFGs is: given a CFG G and a string w, is w a member of $L(G)$?

For simplicity, we assume that G is in Chomsky normal form; that is, all productions in G are of the forms $X \rightarrow YZ$ or $X \rightarrow a$, where X, Y, and Z are nonterminals and a is a terminal. (This restriction does not reduce the expressive power of the formalism.) Under this assumption, the algorithm of Figure 1 solves the CFG recognition problem for the grammar $G = \langle N, V, S, P \rangle$, and string $w = w[0]\ldots w[n-1]$. This algorithm is generally known as the CYK algorithm after its discoverers, Cocke, Younger, and Kasami (see, e.g., Younger, 1967). The basic idea is to maintain an array M (usually called a *chart*) such that $M[i][j]$ stores the grammatical categories that G can assign to the substring $w[i]\ldots w[j-1]$. The loops in lines 2–6 record the possible categories of each word (i.e., each 1-element substring) of w, and the loops in lines 7–16 record the possible categories of successively longer substrings of w.

Let us suppose that the individual instructions in Figure 1 denote basic operations. The complexity of this algorithm is then easily seen to be $O(mn^3)$, where m is the number of productions in G, and n is the length of w. Hence, the general recognition problem for CFGs has complexity $O(mn^3)$; moreover, for every fixed CFG G, the problem of determining whether a string w is in $L(G)$ has complexity $O(n^3)$. We note in passing that our choice of basic operations in this analysis is not entirely innocent. For example, the tests in line 11 read from a list of up to m elements, and the instruction in line 12 writes to such a list. In practice, however, these operations are so fast that it is reasonable to pretend that they are performed in constant time.

```
1 begin cyk(G, w)
2   for i = 0 to n–1
3   for each A → a ∈ P
4    if w[i] = a then add A to M[i][i+1]
5    endfor
6  endfor
7  for i = 0 to n–1
8   for j = i + 2 to n
9    for each A → BC ∈ P
10     for k = i + 1 to j–1
11      if  B ∈ M[i][k] and C ∈ M[k][j] then
12      add A to M[i][j]
13     endfor
14    endfor
15   endfor
16 endfor
17 if S ∈ M[0][n] then return 1
18 else return 0
19 end cyk
```

Figure 1 The CYK algorithm.

Of course, CFGs are not the only way of describing languages. One illustrative alternative is provided by the linguistic formalism known as *Lambek grammar*. The reader is referred to Carpenter (1998) for details; we content ourselves with an informal explanation here. The *Lambek calculus* is a logical system allowing the derivation of various *sequents* involving *category expressions*. For example, Figure 2 shows a derivation of the sequent NP (NP\S)/NP NP → S. Each step in this derivation must be licensed by one of a small collection of rules of inference. Intuitively, a category expression X/Y describes a string that, when a string of category Y is placed to its *right*, will result in a string of category X; similarly, $Y\backslash X$ describes a string that, when a string of category Y is placed to its *left*, will result in a string of category X. Under this interpretation, a sequent $X_0 \ldots, X_{n-1} \rightarrow X$ has the meaning: 'Any string of items of categories $X_0 \ldots X_{n-1}$ is of category X.' Now, a *Lambek grammar G* is a finite list of pairs of the form (v, C), where v is a vocabulary item and C is a category expression. We say that the grammar G *accepts* the string $w = w[0] \ldots w[n-1]$ just in case there exist $C_0 \ldots, C_{n-1}$ such that: (i) $(w[i], C_i) \in G$ for each i $(0 \leq i < n)$ and (ii) the sequent $C_0 \ldots C_{n-1} \rightarrow S$ can be derived in the Lambek calculus. (Again, S is a distinguished start symbol.) Suppose, for example, G contains the pairs (*John*, NP), (*Mary*, NP) and (*loves* (NP\S)/NP). Since NP (NP\S)/NP NP → S is a derivable sequent, it follows that G accepts the sentence *John loves Mary*. The *language of G*, denoted $L(G)$, is the set of strings accepted by G. The recognition problem for Lambek grammars is as follows: given a Lambek grammar G and a string w, is w a member of $L(G)$?

Since the category expressions in a Lambek grammar may be complex, a reasonable measure of the size

$$\dfrac{\dfrac{\dfrac{S \rightarrow S}{NP \rightarrow NP} \quad \dfrac{}{NP\ (NP\backslash S) \rightarrow S}}{NP\ (NP/S)\ /\ NP\ \ NP \rightarrow S}}$$

Figure 2 A derivation in the Lambek calculus.

m of G is in this case the total number of atomic symbols involved in a complete listing of G. Thus, we may reasonably take the total size of the input to the recognition problem to be $m+n$, where n is the length of w. On this measure of input size, it follows from the cut-elimination theorem for the Lambek calculus (Lambek, (1958)) that the recognition problem for Lambek grammars is in the complexity class **NP**. Furthermore, it has been conjectured that this problem is **NP**-hard. If so, it may well be that, unlike the recognition problem for CFGs, no polynomial-time algorithm exists to solve it.

It is known (Pentus, 1993, 1997) that the class of languages recognized by Lambek grammars is identical to the class of languages recognized by context-free grammars. Yet, as we have seen, the recognition problem for CFGs is $O(mn^3)$. This illustrates that the complexity of the recognition problem for a particular grammar formalism cannot be read off in any simple way from its expressive power: CFGs and Lambek grammars have the same expressive power, but their recognition problems may have different complexity. Of course, the expressive equivalence of CFGs and Lambek grammars does tell us that, for a *fixed* Lambek grammar G, the complexity of determining whether a given string (of length n) is in $L(G)$ is $O(n^3)$. (Just get a CFG recognizing the same language as G and use the CYK algorithm!)

These cautionary remarks notwithstanding, commonly encountered grammar formalisms with higher expressive power do tend, unsurprisingly, to exhibit higher recognition complexity. A well-known example is provided by the class of *tree adjoining grammars* (TAGs). A comprehensive introduction to TAGs can be found in Abeillé and Rambow (2000: Chap. 1). But very roughly, a TAG is a finite set of 'local' trees that can be combined into larger trees to license sentences, much as CFGs combine productions (which can equally be thought of as local trees) into phrase structures. The essentially new element in TAGs is the operation of *adjunction*, in which a local tree may be 'spliced' into an existing tree. This leads to an increase in recognition capacity: there exist languages that are recognized by some TAG, but not by any CFG. It also apparently leads to an increase in recognition complexity: the best known parsing algorithms for TAGs have time complexity $O(n^6)$, where n is the length of the input string (Schabes, 1994).

Moving up the expressiveness hierarchy, a *context-sensitive grammar* (CSG) is a set of productions $\alpha \rightarrow \beta$, where α and β are strings of symbols such that $|\alpha| \leq |\beta|$. These productions are interpreted as rewrite rules, in much the same way as productions of a CFG. For comparison, note that, in a CFG, all productions have the form $A \rightarrow \beta$, where A is a nonterminal. Indeed, if we assume (which we may without essential loss of expressive power) that productions in CFGs have nonempty right-hand sides, the condition $|\alpha| \leq |\beta|$ is then trivially satisfied, whence CFGs are a special case of CSGs. The *language* $L(G)$ *of* a CSG G is defined analogously to the context-free case. It turns out that the problem of deciding whether, for a given context-sensitive grammar G and a given string w, w is in $L(G)$ is **PSPACE**-complete. (In fact, it is possible to find a *fixed* context-sensitive grammar G for which the problem of determining whether a given string w is in $L(G)$ is PSPACE-complete.) For a formal definition of context-sensitive grammar and a proof of this complexity result, see Hopcroft and Ullman (1979: 223, 347 ff.).

All the grammar formalisms examined thus far have precise formal definitions, which makes for a clear-cut (though often nontrivial) complexity analysis. However, many mainstream grammar formalisms that aspire to describe natural languages are much less rigidly defined (and indeed much more liable to periodic revision); consequently, it is harder to provide definitive results about computational complexity. Transformational grammar, as outlined in the *Aspects* theory of Chomsky (1965), provides a case in point. Let us take a transformational grammar to consist of two components: a context-free grammar generating a collection of phrase-structure trees – so-called *deep structures* – and a collection of *transformations* that map these deep structures to other phrase-structure trees – so-called *surface structures*. The movement principles in question are too complex for a useful discussion here. The *language of* a transformational grammar G, denoted $L(G)$, can then be defined as the set of strings w such that w is the string of leaves of some surface structure obtained in this way. Analyzing a version of Chomsky's *Aspects* theory, Peters and Ritchie (1973) demonstrated the existence of transformational grammars that can recognize nonrecursive sets. That is to say, the recognition problem for transformational grammars (thus understood) is not even computable. More recent analyses of grammar formalisms in the transformational tradition paint a picture of lower complexity, however. Thus, Berwick and Weinberg (1984: 125 ff.) analyze the complexity of *Government-Binding Grammars*, a formalization of the approach taken in Chomsky (1981), and showed that the recognition problem for such grammars is in PSPACE.

Recent trends in linguistics – particularly within the transformational tradition – have shown a preference for specifying grammars not in terms of generative mechanisms, but rather, in terms of constraints to which sentence structures are required to conform. On this view of grammar, a string w is grammatical

just in case it has a structure that satisfies those constraints. How can we determine the complexity of the recognition problem when grammars are presented in this way? The answer is to employ a formal language: this formal language must be powerful enough to express the constraints constituting the grammar in question, and yet not so powerful that working with it leads to undecidable problems. *Model theoretic syntax* (Rogers, 2003) is a grammar formalism employing this strategy. To understand how it works, we must first rehearse some ideas from formal logic.

Weak monadic second-order logic (wMSO) employs a formal language containing two sorts of variables: those ranging over objects (as in ordinary first-order logic) and those ranging over *finite sets* of objects. For present purposes, we may assume that the 'objects' in question are nodes in a tree that describes the phrase structure of some sentence. We confine ourselves to a language containing binary atomic formulas of the forms $x \in X$, $x \lhd_1 y$ and $x \lhd_2 y$, and unary atomic formulas of the forms $np(x)$, $vp(x)$, etc., where np, vp, etc., form a finite collection of labels. Consider a tree in which each node is tagged with one of these labels. Then the above atomic formulas may be interpreted as follows: $x \in X$ means that node x is a member of the set of nodes X; $x \lhd_1 y$ means that node x is the left sister of node y; $x \lhd_2 y$ means that node x is the mother of node y; $np(x)$ means that x is tagged with the label np; and so on. Formulas are built up from atomic formulas using Boolean connectives and quantifiers (over both sorts of variables) in the normal way. The semantics given above then determine, for a given closed formula and a given labeled tree, whether that formula is true in that labeled tree.

On this view, we can think of a grammar G as a closed formula of weak monadic second-order logic. The set of trees recognized by G is simply the set of trees in which G is true; the language $L(G)$ recognized by G can then be defined as the set of strings w such that w is the string of leaves of some tree recognized by G. The appeal of this approach is twofold. First, wMSO can express many relationships dear to linguists' hearts. For example, it is straightforward to write down a formula $\phi_c(x, y)$, which is satisfied by nodes x and y in a tree just in case x C-commands y. Second, despite its high expressive power, this language is decidable. That is, given any closed formula ϕ, we can effectively determine whether there is a labeled tree in which it is true. (This follows from Rabin's theorem on the decidability of the monadic second-order theory of two successor functions.) It follows that, given any grammar G and any string w, we can effectively determine whether $w \in L(G)$. As might be expected for such a general approach, the complexity of such model theoretic grammars is relatively high. In fact, the problem of deciding satisfiability in this logic is nonelementary. (See Börger *et al.*, 1997: 315 ff., for an accessible treatment.) This complexity result implies that this way of defining grammars is not expressive enough to capture the transformational grammars analyzed by Peters and Ritchie. However, more recent theories in the same tradition may be amenable to formalization within this framework. For example, Rogers (2003) noted that some principles of Rizzi's theory of *Relativized Minimality* (Rizzi, 1990) can be expressed using formulas of the language sketched above.

Recovering Meaning

Most grammars are more than a means of defining a set of acceptable sentences: they also assign one or more levels of structure to those sentences that they do accept. The question then arises as to the computational complexity of recovering that structure.

Consider, for example, context-free grammars. Let G be a CFG. If $w \in L(G)$, then G assigns to w one or more phrase structures representing the derivation of w by the productions of G. It is easy to construct a CFG G for which there exists a sequence $\{w_n\}$ of strings accepted by G, such that the length of w_n is bounded above by some polynomial function of n while the number of phrase structures that G assigns to w_n is bounded below by an exponential function of n. That is, the number of parses produced by a CFG G can grow exponentially. Nevertheless, the CYK algorithm of **Figure 1** shows that the set of phrase structures assigned to any sentence by G may always be compactly represented; moreover, that compact representation may be constructed in time $O(mn^3)$. To see this, note that the chart M in this algorithm specifies every category that G assigns to every substring of w. It is easy to modify the data structures stored in the entries of M so that the elements of $M[i, j]$ are not simply category labels, but rather category labels with pointers to entries in $M[i, k]$ and $M[k, j]$ indicating their daughters. The result will be an acyclic directed graph that can be expanded into a complete list of all the parse trees assigned to w by G in the obvious way. (Trivially, listing all these trees will in general take exponential time.)

Arguably, determining the syntactic structure of a sentence is of little value unless we can use that structure to recover the sentence's meaning. The notion of meaning in general is too vague to admit of immediate formal analysis. However, we might sensibly

begin with the more specific problem of recovering, at least for certain fragments of natural languages, *logical form*, in the sense of producing translations such as the following:

Every boy loves some girl who admires him.

$$\forall x(\text{boy}(x) \rightarrow \exists y(\text{girl}(y) \wedge \text{admire}(y,x) \wedge \text{love}(x,y))) \quad (2)$$

Context-free grammars (and indeed the other grammar formalisms mentioned above) can be modified to yield such logical forms. Approaches vary, but one commonly employed technique is to associate with each vocabulary item an expression of higher-order logic representing its meaning and to associate with each production a prescription for combining the meanings of its daughters. This approach is, more or less, that championed by Montague (1974); for an accessible modern treatment, including an explanation of the relevant principles of higher-order logic, see, for example, Heim and Kratzer (1998). The question now arises: what is the computational complexity of recovering logical forms in this way?

The answer depends on how exactly logical forms are allowed to be represented. If the underlying grammar G is a CFG, then the CYK algorithm can again be modified to produce, in polynomial time, a compact representation of all meanings that G assigns to a given string w, just as for parse trees. However, these representations will not, in the parlance of higher-order logic, be 'β-reduced.' That is, in order to produce ordinary logical translations such as (2), we need to compute the normal forms for the expressions of higher-order logic that our parser yields. And this problem is known to be nonelementary (Statman, 1979). It follows that semantically annotated CFGs can be written for which the problem of computing normalized translations is also nonelementary. In practice, however, the normalization of semantic representations produced by semantically annotated CFGs never constitutes a bottleneck; for most grammars in this form that one is likely to write, computing the semantics entails no essential change in computational complexity. At present, however, there is no systematic formal analysis that can be used to underpin this claim.

Working with Meanings

Finally, even when sentences have been parsed and meanings recovered, the question arises as to the complexity of *using* these sentences. The uses to which language is put are too varied for this problem to admit of any immediate formal analysis. However, we might sensibly begin with the following, more specific problem: given a grammar describing a fragment of natural language, what is the complexity of determining valid entailments involving sentences of that fragment?

A familiar example should help motivate this problem. Consider the set of all English sentences subsumed by the following six schemata, where A and B are any common (count) nouns and S is any proper noun:

Every A is a B.	No A is a B.
Some A is a B.	Some A is not a B.
S is a B.	S is not a B.

Since all sentences in this fragment use the copula to relate two terms, let us call the fragment *Cop*. Cop is, of course, just the language of the Syllogistic. Since the set of sentence types in Cop is finite, the translation from its sentences to first-order formulas representing their logical forms certainly takes only polynomial time. Let e be a sentence in Cop, and let E be a set of such sentences. Let us say that E *entails* e just in case the logical translations of E entail the logical translation of e (in the usual sense of first-order logic). Then we ask: what is the complexity of determining, given E and e, whether E entails e? It is easy to show using standard techniques in logic that this problem is in fact $O(n^2)$, where n is the total number of words in $E \cup \{e\}$.

Now suppose we add relative clauses to Cop, generating such sentences as, for example,

Every philosopher who is not a stoic is a cynic.

Let us call this larger fragment *Cop + Rel*. It is simple to specify Cop + Rel in terms of a grammar belonging to any of the grammar formalisms discussed above. Furthermore, by equipping the grammar in question with a semantics, as discussed in the previous section, we obtain a (polynomial-time) algorithm translating sentences of Cop + Rel into first-order logic, thus defining a notion of entailment exactly as for the fragment Cop. Again we ask: what is the complexity of the entailment problem for Cop + Rel? The answer this time is that it is **Co-NP**-complete. Thus, relative clauses may increase the complexity of determining entailments. Now suppose that we add constructions involving transitive verbs to Cop + Rel, generating sentences such as, for example:

No philosopher who despises some stoic admires every cynic.

Call the resulting fragment *Cop + Rel + TV*. What is the complexity of determining validity now? This

time, it has increased: the validity problem for Cop + Rel + TV is **EXPTIME**-complete.

Likewise, suppose that we add constructions involving ditransitive verbs to Cop + Rel + TV, generating sentences such as, for example,

> No philosopher who despises some stoic recommends every cynic to every skeptic.

Call the resulting fragment *Cop + Rel + TV + DTV*. The validity problem for Cop + Rel + TV + DTV, it transpires, is **Co-NEXPTIME**-complete. Alternatively, suppose we add anaphora to Cop + Rel + TV, thus giving us the ability to recover sentence (2) above. Here, the situation is more complex, because of the need to deal with anaphoric ambiguities. However, it can be shown that, if anaphors are required to take as antecedents the closest possible noun phrase (consistent with the normal rules of binding theory), the result is a fragment in which the validity problem is **Co-NEXPTIME**-complete. Relaxing this restriction results in a fragment for which the validity problem is undecidable.

To be sure, determining entailments between sentences is a rather specialized, not to say abstruse, activity, far removed from the cut-and-thrust of everyday language use. However, the analysis sketched above illustrates some of the broader issues that arise in connection with the computational complexity of natural language. For there is surely more to human beings' considerable linguistic prowess than their ability to recognize membership in sets of strings. Technical details can be found in Pratt-Hartmann (2004).

Language: Semiotics

F Nuessel, University of Louisville, Louisville, KY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

To discuss the semiotics of language entails a consideration of both of these terms. The person most consider to be one of the founders of semiotics, Charles Sanders Peirce (1839–1914), defined semiotics as 'the doctrine of signs.' Simply stated, a sign is something that stands for something else. The Greek philosopher, Aristotle (384–322 B.C.E.), provided a tripartite theory of signs. A sign thus has a physical dimension (a physical object), a referent (what the sign refers to), and an interpretant (what the sign means). Greek physicians, who were the first to discuss signs, used the notion of sign to refer to symptomatology. Certain physical signs stood for particular ailments (redness and swelling might signify a venomous animal bite).

For Sebeok (1994: 17–41), there are six types of signs: signals (the discharge of a pistol to start a race), symptoms (physical signs such as bruises), icons (images, diagrams, metaphors), indexes (weather cock, photograph), symbols (culturally determined meanings accorded to objects, e.g., a cross), and names (how we label ourselves and our physical world). In this article, we discuss several of these sign types as they relate to language.

Language refers to verbal communication. In this sense, it is distinct from nonverbal forms of communication such as kinesics (significant body movement), proxemics (personal space), paralanguage (vocal modification), and codes (Braille and the Morse code). Language thus enjoys a privileged place because it is species unique (*Homo sapiens*).

When we speak of the semiotics of language, we must consider its status with relation to semiotics. Language is a subdomain of semiotics because it is a form of communication. In this article, we look at language as a code that allows us to represent our physical world via linguistic signs (the sounds, words, and syntax of specific languages, and their corresponding written versions) to refer to external reality. What we encode in language reflects what is symbolically significant in a particular culture. Sometimes this symbolization is direct and obvious, i.e., we devise words to express these culturally significant concepts. In other cases, its more subtle meanings are encoded in other ways, e.g., words to indicate social relationships or word order to specify new versus presupposed information.

Language is ubiquitous. All of our daily activity involves language. We use language in all of our interpersonal relationships, the messages that we send to others electronically or in written form, the books that we read, the lyrics of the music we listen to, the advertising that bombards us continually, are but a few examples. Language is the mechanism that encodes culture, the sum total of a group's belief systems, values, and creative activity and it transmits this knowledge intergenerationally.

In this article, we discuss the following aspects of language:

1. A definition and discussion of the notion of language;
2. Linguistic theory;
3. The origination and loss of language(s);
4. Language change, or how language changes through time and space;
5. Pragmatics, or how language is used in different contexts;
6. Neurolinguistics, or the relation of the brain to language;
7. Language games, or the way we play with language;
8. The language of names;
9. The language of advertising.

What Is Language?

What is language? The answer to this fundamental question is not simple. A definition that professors of linguistics often use is the following one: language is an arbitrary system of vocal (or visual) symbols used by the members of a speech community for the purpose of communication. This definition consists of six elements that merit commentary here.

Language is arbitrary because the sounds and forms that different languages use to refer to objects, concepts, and activities are vastly different among the estimated 6000 languages of the world. The relationship of a word and the object or concept to which it refers is thus almost always arbitrary. Although arbitrary in its form–meaning relationship, language is subject to constraints. These controls include limits on the possible type and number of meaningful sounds permissible in a language (20–44 distinctive sounds appear to be the limit). Likewise, word order has limits, and there appear to be six possibilities. The formation of words is also subject to regulation in terms of permissible prefixes, suffixes, and infixes. Second, language is systematic because it employs a few basic rules to create an infinite number of possible combinations, e.g., the phonology (sounds), morphology (word formation rules), syntax (rules that determine the order and arrangement of words within

a sentence), lexicon (the vocabulary of a language), and semantics (the meanings of words in isolation and in context) to formulate meaningful interaction. Third, language is generally vocal, although certain languages used by the deaf (American Sign Language) employ visual cues. Fourth, language is symbolic because its sounds or visual emblems stand for ideas and concepts that reflect the organization of the external world. Fifth, the members of a speech community use a particular language to express their culture, i.e., its thoughts, ideas, and emotions. This community may be local, e.g., the immigrants from another country who retain their first language in order to maintain their identity. Alternatively, the community may be international, e.g., the worldwide community of speakers of Spanish, Italian, or English. Finally, the speech community uses a language to express its feelings, beliefs, and emotions to other speakers of the language.

It should be noted that there is a use of the word 'language' that is applied to certain creative activities. We often speak of the language of film, the language of art, the language of architecture, the language of music, and so forth. This usage is metaphoric because it means that artists employ certain conventions that may be equated with the grammatical rules of a language, i.e., rules for combining the elements of a particular artistic craft into meaningful compositions that may be interpreted by others.

Design Features of Language

Charles F. Hockett (1914–2000) set out to define and differentiate human language and animal communication. In his article on linguistic universals (Hockett, 1963: 8–13), Hockett specifies a set of 16 "design features" for comparing communication systems across species. The latter essay was an expansion of an earlier one in *Scientific American* (Hockett, 1960: 90) in which Hockett originally proposed thirteen design features. These design features provide an excellent overview of the basic elements of language. Table 1 illustrates this typology.

Table 1 Design features of language

Design feature	*Characteristics*
1. Auditory–vocal channel	This feature means that language is an oral–aural set of process rather than a visual, tactile, gustatory, or olfactory procedure.
2. Broadcast transmission and directional reception	This feature means that a verbal signal may be heard within the limits of the ear's ability to detect sound and determine its source.
3. Rapid fading (transitoriness)	This feature means that sounds are temporary and do not last.
4. Interchangeability	This feature means users of a language can duplicate any message they are capable of understanding.
5. Total feedback	This feature means that users of a language can reflect upon what they hear.
6. Specialization	This feature means that the sound waves of a language have the specific purpose of communicating meaning.
7. Semanticity	This feature means that linguistic components carry meaning because they have a systematic reference to objects in the world.
8. Arbitrariness	This feature means that the relationship of the referent and the sound employed to refer to it are independent.
9. Discreteness	This feature means that the sound system of a language consists of a small set of the possible sounds available to it and that these sounds have a pattern of meaningful oppositions, e.g., the consonants /s/, /z/ which are differentiated solely by voicing in the English language.
10. Displacement	This feature means that language may refer to circumstances that are temporally or geographically remote.
11. Openness/ Productivity	This feature means that languages use a finite set of elements (sounds, words, syntax) to create an infinite set of linguistic possibilities.
12. Traditional transmission	This feature means that language is transmitted in a given culture from one generation to another through accepted principles of teaching and learning.
13. Duality of patterning	This feature means that verbal sounds bear no meaning until they combine in a systematic way with other sounds to form meaningful linguistic components such as words and sentences that convey significance in a particular culture.
14. Prevarication	This features means that messages may be false or logically meaningless.
15. Reflexiveness	This feature refers to metalanguage, the ability to comment on language as an entity.
16. Learnability	This feature means that the speaker of one language may acquire another one.

Language and Gender

Sex is a biological category, while gender is a social construct based on sex. Men and women are biologically distinct but gender differences such as dress, behavior, and language are culturally acquired distinctions. What is masculine or feminine in one culture may not be so in another. A fundamental question related to language and gender is whether or not men and women speak differently. In fact, the language of men and women does differ. The way in which it differs falls into several domains. Robin Lakoff's *Language and women's place* (1975) is the groundbreaking study that called attention to differences between men and women's speech habits and the effect that these differences had in terms of power. In the years since its publication, however, several of its claims have been revised based on subsequent empirical research. Various studies show that men and women differ in their conversational styles. Jenny Coates (b. 1942) makes a number of observations about gender differences based on her own research and that of others (Coates, 1993: 138–139). First, context determines speech usage. All-female discourse and all-male discourse is quite different from male–female communication. In male–female conversations, men tend to interrupt women more often. Women employ minimal responses to show support for the speaker and women use hedges (linguistic forms such as *sort of* and *perhaps*). Men, on the other hand, talk more, swear more, and use more commands and imperatives. To be sure, factors such as social status and power affect speech patterns and usage.

Animals and Language

Another issue that merits discussion in this article is whether or not animals other than *Homo sapiens* possess the faculty of language. In his discussion of animal versus human communication, Hockett (1960: 93–95) shows that there are significant differences. A number of psychologists who work with gorillas and chimpanzees argue that these primates can acquire language, in this instance, a form of sign language or artificially created languages. Some of the noteworthy experiments include those listed in Table 2.

Despite claims of communicating with primates via a modified form of human sign language, Sebeok (1981) demonstrates quite persuasively that the animals involved in such experiments are not using language, but rather they are simply responding to subtle cues encoded by the trainer. The most famous claim of interspecies communication is Clever Hans, an Arab stallion from Russia purchased by a man identified as Wilhelm von Osten in 1900. The horse received its name because of a reputed ability to perform mathematical operations as well as an ability to read and to spell. In reality, the horse simply responded to cues from the trainer. The expression 'Clever Hans effect' means that animals behave in certain ways that make it appear to their human captors that they are engaged in language-like functions (Sebeok, 1981: 162–167). Animal–human communication is at best, as Sebeok argues persuasively, conditioned response and not true human linguistic interaction. It should be noted here that Sebeok (1963) coined the neologism 'zoosemiotics' to refer to animal communication. This refers to the sensory signs that animals use to communicate specific messages to other species and to their own species concerning reproduction, territoriality, danger, and so forth.

Semiotics Versus Linguistics

Thomas A. Sebeok (1920–2001) raises an important and sometimes controversial question when he discusses the relationship of semiotics (the study of signs and their uses in representation) and linguistics (the study of language and its usage in culture). Are they coordinate interdisciplines, or is one subordinate to the other? (Sebeok, 1994: 105). Sebeok notes that most would respond that semiotics and linguistics are coequal or that semiotics is subordinate to linguistics. In his carefully crafted response, Sebeok (1994: 106–107) argues that, in fact, linguistics is the subordinate interdiscipline because semiotics deals with the communication of any messages (verbal and nonverbal), while linguistics is concerned only with verbal communication in human languages.

Table 2 Primates and their trainers

Primate	*Trainer*

2. Sarah (chimpanzee)	David Premack (b. 1925)
3. Lana, Sherman, and Austin (chimpanzees)	Duane Rumbaugh (b. 1929) and Emily Sue Savage-Rumbaugh (b. 1946)
4. Koko (gorilla)	Francine Patterson (b. 1947)
5. Nim Chimpsky (chimpanzee)	Herbert S. Terrace (b. 1936)

Linguistic Theory

Linguistic theory has become an important topic for discussion since the 19th century. Because linguistics is considered to be a science, it requires a theoretical apparatus to explain how language functions. It is important to understand the notion of theory. A theory is a hypothesis designed to explain natural phenomena after we observe and describe the basic facts, in this instance, linguistic facts. A credible theory must have the following traits: (1) It must be testable; (2) it must be able to predict; (3) it must be simple; and (4) it must be comprehensive. Though these aspects of theory seem relatively simple, they are difficult to achieve, especially for something as complex as human language.

In the 20th century, linguistic theory received its greatest support from Noam Chomsky (b. 1928), the MIT professor of linguistics. His earliest monograph, *Syntactic structures* (1957) deals with linguistic theory as it relates to syntax. Chomsky envisioned the grammar of a language as a theory of language. Prior to Chomsky's assertion, linguistics was considered to be scientific in the sense of being an accurate description of an observed language. Linguistics is intended to be objective and not prescriptive, i.e., it does not make judgments about how people use their language. Its primary goal is to describe accurately what people say. Chomsky's contribution to linguistic theory goes beyond observation and description to an explanation of language. Chomsky (1965: 4) makes a distinction between competence, the innate ability to produce the sentences of a language and performance, the actual use of language in concrete situations. Chomsky focuses on competence in his theory, while previous linguists focused on performance. He also argues that language is an innate capacity of all humans.

Philosophical Foundations of Linguistics

A review of linguistic research in the 20th century shows that there are two philosophical approaches. First, there is empiricism, the view that we acquire our knowledge of the world through experience, or through the senses. The second is rationalism, the notion that we are born with certain basic knowledge. Throughout the last century, there has been an alternation between these two philosophies. At the beginning of the century, Leonard Bloomfield (1887–1949) published *Introduction to the study of language* (1914), which espoused a rationalistic view of language that Bloomfield called a mentalist viewpoint. Two decades later, under the influence of the behaviorist psychologist, Albert Weiss (1879–1931), Bloomfield completely revised his linguistic perspective to one that he called a mechanistic approach, or an empiricist one in *Language* (1933). This position held sway for nearly a quarter of a century and it finds its most complete articulation in *Verbal behavior* (1957) by the behavioral psychologist, B. F. Skinner (1904–1990). Noam Chomsky faulted every aspect of behaviorist analysis of language, especially its focus on external rather than internal features in his critique of Skinner's book in the journal *Language* (1957, 35:26–58). The debate centered on an empiricist versus a rationalist account of first-language acquisition. Chomsky's approach prevailed because he was able to account for a wide array of linguistic phenomena that previous theories could not explain.

After another quarter century, one of Chomsky's antagonists, George Lakoff (b. 1941) and his colleague Mark Johnson (b. 1949), proposed a novel approach to linguistic theory in *Metaphors we live by* (Lakoff and Johnson, 1980). This empiricist analysis of language research argues that we acquire and use language by interacting with our environment and this interaction is reflected in our language. Its most complete articulation appears in Lakoff's *Fire, women, and dangerous things: what categories reveal about the mind* (Lakoff, 1987), and Ronald W. Langacker's (b. 1942) *Concept, image, and symbol: the cognitive basis of grammar* (Langacker, 2002).

The Origination of Language(s)

In this section, we discuss three ways in which language may arise. The first deals with the species-specific evolutionary development of language. The second addresses contact vernaculars, languages that develop as the result of the contact of two different cultures, e.g., during periods of colonization. The third refers to the creation of languages by individuals to achieve a specific purpose. Finally, we address language death or the loss of a language for various reasons.

Glottogenetics, the science devoted to the study of the origins of language, has come in and out of favor over the years. Because of the plethora of studies on this topic in the 19th century, the Linguistic Society of Paris banned further discussion of it in 1866. Nearly a half century later, in 1911, the Philological Society of London did the same. Nevertheless, in the last quarter of the 20th century, a renaissance of interest in the origin of language took place, as evidenced by the work of Derek Bickerton (b. 1926) *The roots of language* (Bickerton, 1981), and Philip Lieberman (b. 1934) *On the origins of language* (Lieberman, 1975).

Danesi (b. 1946) outlines some of the most common glottogenetic theories of language origination (Danesi, 1993: 5–29). There are at least seven hypotheses:

1. traditional;
2. Otto Jespersen's (1860–1943) enumeration including his own theory;
3. echoic theories;
4. gestural theories;
5. pragmo-communicative theories;
6. scientific approaches;
7. genetics.

Traditional theories about the origination of language include sporadic crude and bizarre experiments designed to determine the first, or earliest human language. These experiments involved the isolation of children from all linguistic contact. Prominent among those who sponsored such cruel trials were Egyptian King Psamtik (663–610 B.C.E.), The Holy Roman Emperor Frederik II (1194–1250), and James IV of Scotland (1473–1513).

Conventional theories of language origins, those that have existed for the longest time, include Otto Jespersen's discussion of four theories (1922: 412–442). First, there is the *bow-wow* hypothesis, which states that speech arose from imitation of natural sounds. Second, the *pooh-pooh* hypothesis, which argues that speech originated from instinctual grunts of pain and pleasure. Third, the *ding-dong* hypothesis, which states speech came about from instinctive oral responses. Fourth, the *ye-he-ho* hypothesis, which asserts that there was a basic need for pre-humans to communicate with their own kind. Jespersen himself offers his own theory, namely, that speech results from the expression of love, play, and affective feelings that developed into song and related forms.

Echoic theories of the origination of speech involve the efforts of pre-humans to imitate the surrounding sounds of these primitive creatures. Certain research into sound symbolism, or onomatopoeia, suggests that there may be shared imitative sounds. Gestural theories argue that the use of gestures, especially the hands, or visual symbolism may account for the origin of language. Pragmo-communicative theories of language origination refer to the development and use of language as necessary to function in society. Scientific approaches to glottogenetics include work by Morris Swadesh (1909–1967) and others who suggested a single source language for the world's languages. Evidence includes scientific principles to reconstruct a proto-language. The comparison of different languages seeks to determine commonalties in the world's languages.

More recently, an evolutionary approach to language origination has become prominent. This approach, represented by Philip Lieberman (1975), argues that language is a mechanism of growth and change that allowed the brain to develop in ways that would enhance survival. Lieberman argues that the development and adaptation of language in the human species are a result of brain structure that allowed humans to generate abstract concepts. The genetic approach to language development is closely associated with Noam Chomsky (b. 1928), who believes that language is a kind of physical organ with grammatical parameters that determine the form of a language.

Pidgins and Creoles

We are able to determine with great accuracy the birth of pidgins and creoles (see McMahon, 1994: 253–283 for a useful discussion). It is necessary to define these terms first. Pidgins are contact languages. They often result from the contact of colonial powers with indigenous populations in their quest to expand their territory. Thus, many pidgins are to be found in Africa, the Caribbean, and Asia. Pidgins result from the contact, most often, of European nations with other nations. In this sense, a pidgin is not the first language of either the conqueror or the conquered. Pidgins represent an effort at some sort of basic communication on the part of both groups. Pidgins are restricted in their usage, e.g., for certain functions such as commerce or trade. Pidgins simplify and restructure two existing languages to create a new language system. The theories about the origin of pidgins are numerous. They include the following basic hypotheses (McMahon, 1994: 255–257):

1. a common nautical language;
2. independent but analogous development;
3. substrate hypothesis, i.e., pidgins combine colonialist vocabulary with indigenous grammar;
4. the monogenetic hypothesis, i.e., all pidgins derive from Sabir a 15th-century Portuguese pidgin;
5. baby-foreigner talk hypothesis, i.e., pidgins represent a simplification of the two languages in contact.

Some linguistic features of pidgins are the following: simple, reduced phonology, reduced vocabulary, no inflectional morphology, and fixed word order.

Creoles, on the other hand, are quite different. First, they represent a highly developed and sophisticated linguistic system with native speakers. Their phonology, morphology, syntax, and lexicon have all of the characteristics of ethnic languages. In this sense, creoles are distinct from pidgins. They still

have a relatively simple phonology but their vocabulary is rich. They have an array of inflectional affixes to indicate plural formation and verb tenses. Furthermore, their syntax is more elaborate and they have embedded sentences and variable word order. Subsequently, they spawn grammars, dictionaries, and creative literature. Some examples of creole languages are the following:

1. Creole Tok Pisin, which means 'speech business' is one of the official languages of Papua, New Guinea and is an admixture of English, Melanesian languages, and German;
2. Haitian Creole, a combination of French and African languages;
3. Hawaiian Creole, a combination of English, Hawaiian, and various Asian languages.

The study of word origins is known as etymology.

Pidgins and creoles are important examples of the origination of new languages that are both accessible to researchers and provide insights into how language first developed. Furthermore, they offer concrete cases of language change in progress. Bickerton, whose work on the origins of language was mentioned above, uses data from pidgins and creoles to support his linguistic bioprogram hypothesis, i.e., all people possess an innate syntax and semantics component.

Planned Languages

Just as we can document the emergence of pidgins and creole languages, we can do the same for created languages, often to the very year of their inception, A planned language is one that is deliberately created by an individual for a specific purpose. At least 900 language schemes have been devised since the 16th century. Umberto Eco (b. 1932) writes about planned languages in *The Search for the perfect language* (Eco, 1995). In that volume, Eco discusses four types of languages:

1. the rediscovery of languages (Hebrew);
2. the reconstruction of languages (Indo-European);
3. languages constructed by individuals including *a priori*, and *a posteriori* languages;
4. so-called magic languages (secret languages endowed with properties of mysticism).

There are essentially two basic types of planned languages. First, there are *a priori* languages, those that are composed entirely of invented elements not found in any existent language. Several examples of this type of language exist. One is Timerio invented in 1921 by a Berlin architect named Tiemer who used a numerical scheme for his *a priori* language. Thus, in Timerio, 1-80-17 means "I love you."

A second general category of invented language is called *a posteriori*. These languages draw upon the grammar, vocabulary, and syntax of natural languages. The best exemplar of this type of planned language is Esperanto, which merits some discussion here because it is the only successful language of its kind. Esperanto is the invention of Dr L. L. Zamenhof (1859–1917), a Polish physician. As a Jew, he suffered at the hands of anti-Semites during his childhood. As a result of his negative experiences, he concluded that a universal auxiliary language would enhance communication and reduce animosity. In fact, his language had two purposes. The first is value-oriented, i.e., contributing to world peace, justice, and the brotherhood of humanity. The other is its norm-orientation, i.e., the use of the language for commerce, travel, and international conferences. The Esperanto language took its name from the pseudonym adopted by Zamenhof to protect his identity. It means "one who hopes." Its vocabulary derives from Romance, Slavic, and Germanic languages. Esperanto has 16 basic rules in its grammar. It uses many prefixes, infixes, and suffixes to create new words from its basic core vocabulary. The language is the only successful created language and it has a rich literature (original works and translations of the most important literary works from ethnic languages). The current number of Esperanto speakers worldwide is estimated to be between 120,000 and 2 million, depending upon the method of calculation. No other planned language has achieved this degree of success.

The following brief selection is from the poem entitled 'La Espero' ('hope') written in 1890 by Zamenhof (Table 3), and considered to the Esperanto anthem. My English translation appears next to it.

Language Death

While glottogenetics is concerned with the origination of language, at the other end of this continuum, the phenomenon of language death has become a matter of growing ecological concern. Wallace F. Chafe (b. 1927) was among the first to

Table 3 The Esperanto anthem 'La Espero' '*Hope*'

La Espero	Hope
En la mondon venis nova sento,	*A new feeling came into the world,*
Tra la mondo iras forta voko;	*A strong voice sounds through the world;*
Per flugiloj de facila vento	*On wings of a slight wind*
Nun de loko flugu gi al loko	*May it now fly from place to place.*

comment on the eventual loss of numerous indigenous languages in North America (Chafe, 1962).

The sociolinguist, Tove Skutnabb-Kangas (b. 1940) addresses the issue of language death in great detail. She (Skutnabb-Kangas, 2000: 46–50) presents a state-of-the-art assessment of the status of endangered world languages today. She cites Michael Krauss (b. 1934) who proposes three categories of languages (Krauss, 1992: 5–7):

1. moribund, which are languages that children no longer acquire;
2. endangered, which are languages that will likely not be learned by children in this century;
3. safe, which do not belong to the first two categories.

David Crystal (b. 1941) poses the question (Crystal 2000: 26–67): "Why should we care about language loss?" He provides five reasons for preserving languages:

1. they express ethnic identity;
2. they preserve history, especially in oral cultures;
3. they contribute to our knowledge of the world;
4. they are interesting expressions of humanity;
5. they contribute to diversity.

Among Crystal's (2000) recommendations for the preservation of endangered languages are the following:

1. increase the prestige of endangered languages in the superordinate community;
2. ensure their presence and use in education;
3. enhance their power in the community;
4. ensure that speakers of endangered languages are literate in that language;
5. use electronic technology for their dissemination.

The reasons for language death are varied. One reason may be a shift from an indigenous language to a recently introduced one, e.g., by a colonialist power, and it makes sense to acquire the new language for practical purposes. In this situation, there is likely to be a period of sustained bilingualism. Second, there may be sudden death. MacMahon (b. 1964) (1994: 286) notes the example of the loss of the indigenous languages Lenca and Cacaopera in El Salvador in 1932 when Indians were murdered and the use of either language represented mortal danger to the survivors. McMahon (1994: 287–291) also discusses language suicide that involves two related languages, one prestigious and the other not. This process is sometimes labeled decreolization. A classic example is the competition of English with Guayanese Creole in the western hemisphere. A third example is language murder. Nancy Dorian (b. 1936) has researched East Sutherland Scottish Gaelic, which is rapidly losing its battle for survival to English (McMahon, 1994: 294–303).

The loss of language means the loss of an entire culture, or at least the loss of that culture as an ongoing source of creativity and inventiveness though cultural vestiges such as literature and art will survive. Language death occurs for a variety of reasons. It may be a deliberate act of a national government in order to promote unity and solidarity and to exterminate dissidents of a minority group who may seek autonomy or independence, e.g., Francisco Franco's (1892–1975) suppression of regional languages in Spain (1939–1975).

Language Change

We are all aware of language change when we travel. The English of Boston, London, Melbourne, and Calcutta are quite distinct. When we take survey courses in English literature, we see different forms of English in Beowulf, Romeo and Juliet, and a modern novel.

Language is not static. It changes from place to place and generation to generation. Spatial language change involves synchronic linguistics, i.e., changes in contemporary language. Historical change is diachronic change, i.e., language changes over time. Ferdinand de Saussure (1957–1913) added to our knowledge of language change by establishing the distinction between diachronic and synchronic language analysis.

There have been many efforts to explain language change. In the 19th century, German linguists proposed linguistic laws to explain diachronic language change. Rasmus Rask (1787–1832), for example, first proposed a law of sound correspondences in Indo-European. Subsequently known as Grimm's law after Jakob Grimm (1785–1863), this set of sound correspondences specifies how certain consonants appeared in modern Germanic languages such as English, Dutch, and Swedish. Although Grimm's law explained many changes, it had exceptions. The Danish linguist, Karl Verner (1846–1896) was able to find the generalization to Grimm's law to make it exceptionless. This approach to language change was labeled comparative grammar by the German scholar Friedrich Schlegel (1772–1829).

André Martinet (1909–1999) suggested a tension between the speaker and the hearer as a factor in language change, i.e., the speaker wants to expend minimal effort in articulation while the hearer seeks maximum differentiation. In *The sound pattern of English* (Chomsky and Halle, 1968), Noam Chomsky and Morris Halle (b. 1923) argue that language

change is grammar change, i.e., there are changes in the grammar of a language that account for phonological change. These grammatical changes may involve rule addition. These authors provide evidence of this type of change in English, especially the Great English Vowel Shift occurred because of rule addition.

In the past four decades, sociolinguists, those who study the use of language in various social contexts, have added to our knowledge of language change. The approach of the sociolinguist is to look at socioeconomic factors to try to explain language change. Factors that come into play include prestige of a language register, educational background, group identity, interethnic contact and influence, to name but a few (McMahon, 1994: 225–252).

Pragmatics

Levinson (b. 1947) points out that the modern usage of the term 'pragmatics' derives from Charles Morris' (1903–1979) work (Morris, 1938) on semiotics (Levinson, 1983: 1). Levinson (1983: 5) goes on to note that it is difficult to provide a succinct yet comprehensive definition of the term 'pragmatics.' Levinson (1983: 9, emphasis in original) provides the following definition of pragmatics that is a useful one: "Pragmatics is the study of those relations between language and context that are **grammaticalized**, or encoded in the structure of a language."

In simple terms, pragmatics is the subdomain of linguistics that examines how language is used in specific social contexts. Our parents are usually responsible for teaching us pragmatics and they often do so when they direct us to use certain words and phraseology in particular situations, e.g., when we should address people by their first name, or by their last name with an appropriate title (Mr, Mrs, Miss, Ms, Doctor, Reverend, and so forth). This particular form of pragmatics is labeled politeness. Politeness is often encoded in languages of the world. When you study the Romance languages, for example, you learn that there two ways of expressing the English word 'you' (English had two ways also 'you' and 'thou,' which still exist in Amish English). In French, there are the forms '*tu*' and '*vous*'; in Spanish there are the forms '*tú*' and '*usted*'; and in Italian '*tu*' and '*Lei*.' These familiar and polite forms use different verb forms and this is a very difficult concept for Anglophones to acquire, especially when they are acquiring a second language.

When we want someone to do something for us, we use different forms of language to achieve our objectives. There is a hierarchy of linguistic forms that represents the social or official status of the speaker and hearer. These formal differences correspond to a scale politeness (Brown and Levinson, 1987) that conforms to social power structures. Thus, there is a direct correlation between linguistic form and power status. The scale of directness moves from most direct to most subtle with a series of intermediate points along this scale. First, there are direct commands or imperatives that coincide with a superordinate–subordinate status. Examples of this linguistic context would include police and military personnel who use the familiar imperative to make the hearer comply with a certain command, e.g., *stop*! or *halt*! Second, are performatives, e.g., *I'm asking you to move that chair.* Third, there are obligation statements, e.g., *you'll have to move that chair.* Fourth, there are suggestions, e.g., *why not move that chair.* Fifth, there are hints, e.g., *the chair is still there*. Finally, there are mild hints, e.g., *we don't want too much furniture in this room*. Table 4 illustrates such a scale in which the first is most direct and the last is least direct.

Imperatives, which are the most direct requests, have a certain linguistic form, i.e., a verb with no subject, e.g., *move!* Milder requests take the form of statements, e.g., *there is more space in the living room* (request that someone move). Likewise, questions may also be requests, e.g., *where's the salt?* (meaning, 'please pass the salt'). In *Toward a linguistic theory of speech acts* (Sadock, 1974), Jerrold Sadock (b. 1942) calls the latter whimperatives because they frequently uses a *wh*-question (what?, where?, why?, and so forth) word in their formulation.

Jenny Thomas (b. 1948) points out that when we acquire a second language, we often fail to learn certain pragmatic strategies such as the appropriate forms of politeness in the target language that she calls pragmatic failure (1983: 99). This means that although we may have total command of the phonology (the study of the sound system of a

Table 4 Scale of politeness for requests

Most direct	→	→	→	→	*Least direct*
Direct command (imperative) 1	Performative statement 2	Obligation statement 3	Suggestion 4	Hint 5	Mild Hint 6

language) and syntax (the study of the order and arrangement of the words of a language) of the second language, we may not know which forms to use in the appropriate contexts, with the result that we project an image of an abrupt or impolite person. Even the most fluent person may be unsuccessful if he or she ignores these subtle pragmatic rules of politeness.

Neurolinguistics

Neurolinguistics is the study of the relationship of the brain to language. The brain orchestrates the complex operations involved in comprehending and producing language. When it suffers damage (brain attacks or strokes, Alzheimer's disease, and other maladies), it fails to direct orderly speech operations. This results in failed comprehension by the speaker and it also means that the hearer will not be able to understand the messages sent by a speaker with a neurolinguistic affliction.

As we noted previously, physicians are semioticians. Their task in diagnosis is to decode what outward symptoms stand for. A physical symptom signifies something other than itself. In medicine, this semiotic tradition goes back to the ancient Greeks. Hippocrates (460–377 B.C.E.) provided the first definition of a symptom, and Galen (139–199 C.E.) followed this tradition. Physicians examine superficial signs to arrive at a diagnosis. In fact, the classical Latin symptoms of disease included the following:

1. *rubor* 'redness';
2. *dolor* 'pain';
3. *fervor* 'fever';
4. *tumor* 'swelling.'

These symptoms may correspond to a variety of maladies including allergies, infections, and broken bones, to name but a few possibilities. Symptomatology remains an important part of the medical curriculum today. It exemplifies semiotics perfectly because the symptom stands for something else. A precise determination of what symptoms stand for is a physician's daily task.

Speech pathology is that branch of medicine that seeks to provide clinicians with an exact set of correspondences of symptoms or signs to specific physical malady. In *Linguistic encounters with language handicap* (Crystal, 1984), David Crystal discusses the need for more work on symptomatology in the domain of speech pathology. In particular, Crystal notes the need for good transcription of speech dysfunction and standardized typologies of these maladies.

Aphasia (Greek 'no speech'), is partial or total inability to produce meaningful speech. It is occasioned by damage to specific areas of the brain. Specific parts of the brain control speech functions. One is Broca's area, which controls the musculature of thethroat and mouth for speaking. This area was named for the French scientist Pierre-Paul Broca (1824–1880) who found a correlation between aphasia and damage to a specific area of the brain, reported in a paper published in 1861. Broca's aphasia has several manifestations: limited word use, frequent pauses, short sentences, and nonfluent speech. In 1874, 13 years later, the German scientist, Carl Wernicke (1848–1904) published a paper that linked a specific type of speech disorder to damage in the area now called Wernicke's area. Wernicke's area controls speech comprehension. In simple terms, its manifestations include the loss of comprehension of spoken language, the inability to write, the loss of silent reading comprehension, and the distortion of speech.

When people lose the ability to produce or comprehend speech, they are unable to communicate appropriately with their family, friends, and associates. Such speech disfluencies affect social interactions and they need to be addressed clinically.

Language Games

Language games constitute an important part of human behavior. Children engage in them and they are a meaningful part of first-language acquisition, while adults enjoy them for their entertainment and creative value. Language puzzles are enormously popular and they may be found in magazines dedicated to this activity such as *Games* or as regular features in serious journals such as *Scientific American*. Puzzles may be nonverbal or verbal. Mathematical problems and logical problems are nonverbal though they may be presented in story form to make them easier to comprehend verbally. Our interest here is verbal puzzles, games that you can play with language. We provide several examples of such games here (see Danesi, 2002 for further discussion). Language games provide amusement and develop linguistic skills for those who create them or play them. An excellent language exercise is to try to create your own language games.

Riddles

A riddle is a statement or a question intended to puzzle the hearer. The classic riddle is the Riddle of the Sphinx, believed to be the oldest known puzzle. The Sphinx was an ancient mythological monster.

This beast lurked near the entrance of the city of Thebes and, under penalty of death, required of those who wished to enter that they answer the following riddle: "What has four feet in the morning, two at noon, and three at twilight?" The answer, of course, is man, because he crawls on all fours as a child, walks upright as an adult, and uses a cane in later life. Books of riddles abound and riddling is a favorite activity of children.

Palindromes

Palindromes are phrases or sentences that may be read the same forward and backward. They have a long history, and the originator of this form of linguistic amusement is reputed to be Sotades, a poet from Alexandria in the 3rd century B.C.E. The classic example of this type of word game is "A man, a plan, a canal – Panama."

Anagrams

An anagram (Greek for reversed letters) is a language game in which the letters of an existing word are rearranged to create an entirely new word (spit → tips) or a rearrangement of the letters of an existing word or phrase to create a new phrase or sentence. With respect to the second type of anagram, it is common to use the name of a well-known figure to create a phrase or sentence that captures the essence of that person. The rearrangement of the title of a well-known piece of literature may encapsulate its content. Two examples of this type of language game come from Bergeson's (1973: 77, 81) book *Palindromes and anagrams*: the title of Jules Verne's (1828–1905) famous novel *Twenty thousand leagues under the sea* → "Huge water tale stuns. End had you tense" and William Shakespeare (1564–1616) → "I ask me, has Will a peer?"

Word Ladders

Word ladders, sometimes called *doublets* or *word ping-pong*, involve the change of a single letter of a word by changing one letter to create an entirely new word. Figure 1 is a simple example of this type of language game (each letter change appears in boldface type).

STI**L**L
ST**A**LL
STAL**K**
STAL**E**
STA**K**E
S**N**AKE

Figure 1 Word ladder (word doublet, word ping-pong).

Word Squares

Word squares are words of equal length that read the same vertically and horizontally. The longer the word, the more challenging is the task. Figure 2 is a typical example of this type of language game.

Crossword Puzzles

Arthur Wynne (1862–1945), a journalist for the *New York World*, is credited with the invention of the now ubiquitous crossword puzzle, although he called it a word cross. His first puzzle appeared in that paper on December 21, 1913. The best known enigmatologist is Will Shortz (b. 1952), successor to Eugene T. Maleska (1916–1993), who is responsible for the prestigious *New York Times* crossword puzzle.

The crossword puzzle consists of a set of clues that may be thematic and that can be quite challenging. In fact, there is an annual crossword puzzle contest. The reader must write the appropriate word either vertically or horizontally. The simple crossword puzzle in Figure 3 illustrates this type of word game. The clues relate to linguistics and language and the answers can be found in this article.

Lipograms and Univocalics

A lipogram is a language game in which the author writes a creative work by deliberately omitting a particular letter (lipogram) of the alphabet or by using a single vowel (univocalics). The Greek poet Lasus (538 B.C.E.-?) is perhaps the first author to write in this fashion. He wrote two poems, an ode to the Centaurs (Greek mythological animal with head and arms of a man and the trunk of a horse) and another work to the Ceres (goddess of agriculture) in which the letter *s* was deliberately omitted. Many other writers have imitated this practice.

Oulipo, alternatively written as *OuLiPo* (abbreviation of the French *Ouvroir de Littérature Potentielle* 'work of potential literature'), is a group of creative writers in France who seek to write distinctive creative works subject to various constraints and regulations (Motte, 1998). The origin of this group may be traced to a meeting of diverse professionals who convened at Cerisy-la-Salle for a colloquium on the work of the French author Raymond Queneau (1903–1976) in September 1960. One intriguing example of their literary tradition is the novel *La disparition* (Perec, 1969) written by George Perec (1936–1982). What makes this literary work so interesting is the

MET
EKE
TEN

Figure 2 Word square.

fact that the author wrote the novel (300 pages long) without using the vowel *e*. Furthermore, Gilbert Adair (b. 1944) translated the original French work into English as *A void* (Adair, 1995), again without using the letter *e*. In his review of the English translation in *Time* magazine (Gray, 1995: 74), Paul Gray (b. 1930) did not use the letter *e*. The following passage of Gilbert Adair's English translation of Perec's novel (Adair, 1995: 3) illustrates this technique.

> Incurably insomniac, Anton Vowl turns on a light. According to his watch it's only 12.20. With a loud and languorous sigh Vowl sits up, stuffs a pillow at his back, draws his quilt up around his chin, picks up his whodunit and idly scans a paragraph or two. . . .

Names

The study of names is called onomastics. Names are one of the most significant aspects of language. In order to refer to people, objects, concepts, and places, they must have a name. Names pervade our linguistic existence. We use names to label and categorize the world around us.

Personal Names

Personal names include family names, or surnames, and given names (first names and middle names). Names give us identity and it is an important ritual worldwide. Surnames denote lineage, while given names provide us with personality and individuality.

Figure 3 Linguistic crossword puzzle.

Given names often reflect name fads, i.e., certain names are popular during certain eras and may fall out of favor during others. The popularity of certain names often reflects those of well-known personalities of a particular time, most often entertainers (film stars, singers, and so forth). Parents often seek to give their children names that do not deviate from perceived social norms of a particular era so that their children are not burdened by unpleasant teasing from their peers. The U.S. Social Security Administration provides a comprehensive listing of given names that dates to 1880. We have provided a list of the most popular male and female given names for both 1900 and 2003 in Table 5. Although these names represent a single country, similar lists may be found for other nations as well.

Name Changes

Name changes represent another aspect of onomastics. The reasons for changing one's name are varied. People may not like their given name, especially if it is unpopular or somehow perceived to be aesthetically displeasing. A family name may have an unpleasant connotation, e.g., Hogg, Hitler, Stalin, and so forth. Entertainers may have names that are difficult to pronounce or spell. Furthermore, they seek a name that is easy to remember and that has some positive connotation, e.g., Issur Danielovich Demsky (Kirk Douglas [b. 1916]), or Francis Gumm (Judy Garland [1922–1969]). A third reason for such changes may be for criminal ends, e.g., to defraud someone of money, or for the purpose of avoiding identification and detection. A name change is a significant semiotic act because it alters our personal and public identity.

Language of Oppression

The language of oppression involves the naming and labeling of groups in distorted and negative ways so that the dominant and oppressing group may have control over the oppressed one. Haig Bosmajian (b. 1929) notes that the power to name one's foe means that you can define it (Bosmajian, 1974: 5–6). This linguistic power transfers self-definition from the oppressed group to the oppressor, often with severe consequences.

Language may be used to express prejudice and discrimination. It may encode prejudice (negative attitudes based on erroneous information about a particular group), or discrimination (acts intended to cause harm to a group, e.g., failure to hire, or even to eliminate an entire group of people as was the case with The Holocaust).

Table 5 Most popular male and female given names in the United States

Boys' names (1900)	*Girls' names (1900)*	*Boys' names (2003)*	*Girls' names (2003)*
1. John	1. Mary	1. Jacob	1. Emily
2. William	2. Helen	2. Michael	2. Emma
3. James	3. Anna	3. Joshua	3. Madison
4. George	4. Margaret	4. Matthew	4. Hannah
5. Charles	5. Ruth	5. Andrew	5. Olivia
6. Joseph	6. Elizabeth	6. Joseph	6. Abigail
7. Frank	7. Marie	7. Ethan	7. Alexis
8. Henry	8. Rose	8. Daniel	8. Ashley
9. Robert	9. Florence	9. Christopher	9. Elizabeth
10. Harry	10. Bertha	10. Anthony	10. Samantha

Frequently, words to describe these acts become part of the language long after the behavior associated with them have occurred. In the past 40 years, at least two terms that refer to categories of long-standing prejudice and discrimination, sexism, and ageism, have entered the English language and now appear as dictionary entries.

The language of American Indian derision, and the language to disparage the disabled are other domains in the language of oppression. The derisive language aimed at minority groups often reflects the behavior or the appearance of the targeted group. The linguistic terms to deride these groups, often metonymic (the use of the part for the whole) in nature, serve to focus on some superficial aspect the oppressed group's appearance such as skin color. These metonyms may also allude to cultural habits such as clothing, eating habits, or some other equally unimportant external custom of the group.

Bosmajian (1974) notes that legal language often encodes prejudice and discrimination. In fact, officially promulgated laws provide strong evidence for the language of oppression, as evidenced by anti-Semitic legislation and official decrees in Nazi Germany, sexist language in U.S. laws, and the racist Jim Crow laws of the post Civil War in the United States, and U.S. court cases that excluded Native Americans from civil rights in the United States.

The Language of Advertising

Danesi (2000: 6) defines advertising as "[t]he making of public announcements designed to promote the sale of specific commodities or services." Advertising has a long history, and it can be traced to ancient times. This form of commercial publicity was at first oral. Prior to the invention of the printing press, people proclaimed their wares in public by shouting. Once relatively inexpensive paper reproduction became available, printed advertising became ubiquitous. Advertising as a formal corporate service first appeared in the 19th century. Volney P. Palmer (1799–1864) started the first agency in 1841. At the end of the 19th century, advertising was a full-time business. At that time, branding of products was the most important task. This changed in the 20th century when companies sought not only to identify their products but also to persuade the public to buy their products and services. Danesi (2000: 7) points out that advertising is now "a dominant form of social discourse."

Advertising thus involves the use of language to advocate, promote, persuade, engage, and interact with potential customers. Advertisers accomplish this task with language as well as other means. We shall examine this process now. Prior to discussing language *per se*, it is necessary to consider how advertisers achieve their goal of convincing the public to pay attention to their product, and then, to buy it. We receive information about our external world through our five senses (hearing, sight, smell, taste, and touch). In its earliest form, much of advertising involved a combination of textual and visual materials. In the 20th century, this process became more sophisticated. Advertisements for perfumes and colognes included magazine inserts that allowed people to smell the product. Likewise, certain popup advertisements provided a three-dimensional component to advertising. It has become impossible to escape advertising in the 21st century. It is literally everywhere. In the print media, it may be found in the traditional places such as magazines, newspapers, flyers, and so forth. In the broadcast media, it appears in television, radio, and film. Product placement, the subtle or not so subtle insertion of certain well-known products in films and television programming, means that advertising is ubiquitous.

Roland Barthes (1915–1980) specifies two types of messages encoded in advertising, the quintessential semiotic text (Barthes, 1964). These are the linguistic message and the visual image. The latter involves the

visual depiction of the product or service and a second, implied or unstated connotation, i.e., what the product means to the consumer. Tobacco advertising has been quite effective in delivering this hidden, coded message. Forty years ago, the Marlboro man depicted a virile cowboy who personified masculine virility. By association, using this product would bestow on the user these same qualities. More recently, tobacco products have evoked a notion of coolness (the image of a person who is popular and who engages in peer-approved activities) to effect the connotative message. In fact, certain messages involving a hip-hop lifestyle are directed at inner-city youth in an effort to recruit young adults to use these products.

Our interest here is the use of language to promote products and services. As noted above, advertising encodes overt and covert messages to the consumer. At the superficial level, advertising tells the public what the product or service will do: clean, provide easily consumable food, and so forth. At the covert level, advertising evokes popular myths. If we use a product, it will make us resemble, or perhaps become, certain archetypal figures who signify virility, femininity, and so forth. The models and the actors convey this image to the consumer. The verbal messages (including warnings) tell us one thing, while the visual messages implicit messages convey other more significant ones about lifestyle.

Truth in Advertising

Representing a product or service is now subject to some minimal requirements of truthfulness. Most countries have governmental agencies that exert some minimum standards of honesty for product and service promotion. While overt lying is thus not permitted, compliance with legal regulations often involves the skillful use of language and visual accommodation to meet legal requirements. We now know that certain products may be harmful. Smoking cigarettes, for example, may cause death from a variety of diseases, including cancer. When first required to place warning labels on their product, cigarette companies simply placed somewhat ambiguous statements on the packages. Subsequently, these warnings became more specific and prominent as legislation became more demanding.

The warnings and disclaimers in advertising are often hidden through various media artifacts. In print media, they appear in small print at the bottom of a colorful and appealing pictorial presentation. In non-print media, they appear as white, verbal text against a light background for a moment at the end of announcement or in a rapid hyper-speech enumeration at the end of the main message, thus making it difficult to comprehend.

Producers of alcoholic beverages now seek to avoid lawsuits by inserting language about responsible drinking unobtrusively into their advertisements. Advertisements for pharmaceutical products do the same by mentioning sometimes long lists of side effects (sometimes including death) in their product announcements.

Product Names

A trade name is very important. Adrian Room (b. 1933) specifies six criteria for product names (Room, 1982: 15–16):

1. visual comprehension (easy to read);
2. easy to pronounce in most languages;
3. avoidance of unacceptable or absurd meanings;
4. positive references;
5. ease of recall;
6. conformity to legal requirements for official registration.

Trade names fall into three basic groups. The first is the personal name, i.e., the name of the founder of a company, e.g., *Sears*®. The second is a name that represents some special feature of the product, e.g., *Sunkist*® or *Safeway*®. The last is the arbitrary name, i.e., one with no obvious reference, e.g., *Exxon*®.

Other factors go into trade names. Spelling, for example, is important. Certain consonants are preferred, e.g., X (*Xerox*®) and K (*Kodak*®). X is a letter that corresponds to several sounds [z] and [ks]. Other letters, L, M, N, have syllabic value and thus they convey more than one sound. Morphology, of the formation of words, is an important part of product designation. Pharmaceutical products tend to end in suffixes such as *-ine* (*Listerine*®, *Dramamine*®) or *-in* (aspirin). The semantics, or meaning of a product or service name, is also quite important. A product name may involve snob appeal, e.g., *Lord and Taylor*®. Trade names may identify the function of the product or service, e.g., *Chem-Lawn*®.

Car names encode hierarchies that usually correspond to price ranges and status, e.g., *Chevrolet*®, *Pontiac*®, *Buick*®, and *Cadillac*®. Within a given car line, there exist hierarchies also (make, line, model). *Chevrolet*® thus has various subdivisions including *Aveo*®, *Cavalier*®, *Malibu*®, and *Impala*® within its standard line. In his classic sociological class, *The status seekers* (Packard, 1959: 313), Vance Packard (1914–1996) noted that "the automobile makers built up a status hierarchy for automobiles that was well understood by the public."

Concluding Remarks

Language is an evolutionary mechanism that *Homo sapiens* developed to enhance survival. It is a multifunctional tool that allows us to interact as social beings with other people in our daily lives. Various technologies have allowed us to encode language in order to record past events and to refer to previous events and the circumstances that surround them. Written language thus preserves our past. Modern technology also allows virtually instantaneous contact with other people globally.

What is important about language is the fact that it encodes cultural content in various, often subtle ways. Our choice of words and specific grammatical forms represent our perceptions of the world. Our linguistic interactions and usage reveal us to the world. Most of Erving Goffman's (1922–1982) research deals with communication and language, either directly or indirectly (*Behavior in public places*, 1963). He makes the point that all of our social intercourse revolves around language, or even occasionally, on the lack of it, i.e., silence. When we use language, we encode significant amounts of collateral information about ourselves and our beliefs in indirect ways. Likewise, when we decode linguistic messages, we interpret a great deal about the message through word choice and grammatical form. The form of the message sometimes provides more information than its content.

Languages for Specific Purposes

J Engberg, Aarhus School of Business, Aarhus, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Defining the Object

The object of study for the branch of applied linguistics that is covered by the heading 'Languages for Specific Purposes' is multi-faceted. The many facets are a consequence of the fact that this discipline looks at (in principle all) aspects of actual communication in specialized discursive domains. To say that discursive domains are specialized means that it is possible to become a specialist in the domain, through education, training, or experience. This definition covers primarily professional areas, but also nonprofessional areas like hobbies. The fact that not a focused part of the human linguistic competence, but the totality of aspects involved in communication in the described settings is the potential object of study, gives studies into the field a very wide range. However, two main poles may be isolated in the landscape of LSP research, around and between which different approaches and projects are located:

- One pole sees LSP as supplementary language skills that are applied when producing texts in specialized situational settings in order to realize specific purposes. The basic assumption is that language is generally used in the texts according to the ordinary rules known to all language users (Language for General Purposes, LGP), but the ways words are connected and the words are specialized. This approach is generally meant by the English term used to designate the object of study, viz., 'Language for Specific Purposes.' The concept centrally behind this term is closely connected to language teaching for professional purposes, where speakers of, e.g., English as a foreign or second language have to learn (additionally) how to use language in areas where they are going to work. In other words, scholars tending to this pole concentrate upon the specific linguistic differences between language used in different settings.
- The other pole is more closely connected to the concept of specialized meaning. The center of this pole is the concept meant by the German term *Fachsprache*, i.e., domain or subject specific language. This concept lays more weight upon the specialized meanings constituting a domain and upon the relations between these meanings and the linguistic choices conventionally made by the agents of the domain. In other words, the view of the scholars tending to this pole is more global, they are rather looking at the language of a domain as a general reflex of the domain and the specialized meanings constituting the domain. This latter view is more discourse oriented in its approach to its object.

The two poles describe two original, fairly different approaches to this object: the first mentioned approach, concentrating upon text production in specialized situational settings, is connected to language teaching, especially to teaching a foreign or second language in connection with vocational training, university studies, etc. A major interest in this approach is to create knowledge about the specific needs to be covered in such specialized language classrooms, in order to make this kind of language teaching as efficient as possible. The study of domain specific language use comes in handy as a linguistic basis for such specialized courses. This kind of language teaching is mostly connected to learning English. For one thing, this occurrence is due to the fact that a number of countries with multiple national

Languages for Specific Purposes

J Engberg, Aarhus School of Business, Aarhus, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Defining the Object

The object of study for the branch of applied linguistics that is covered by the heading 'Languages for Specific Purposes' is multi-faceted. The many facets are a consequence of the fact that this discipline looks at (in principle all) aspects of actual communication in specialized discursive domains. To say that discursive domains are specialized means that it is possible to become a specialist in the domain, through education, training, or experience. This definition covers primarily professional areas, but also nonprofessional areas like hobbies. The fact that not a focused part of the human linguistic competence, but the totality of aspects involved in communication in the described settings is the potential object of study, gives studies into the field a very wide range. However, two main poles may be isolated in the landscape of LSP research, around and between which different approaches and projects are located:

- One pole sees LSP as supplementary language skills that are applied when producing texts in specialized situational settings in order to realize specific purposes. The basic assumption is that language is generally used in the texts according to the ordinary rules known to all language users (Language for General Purposes, LGP), but the ways words are connected and the words are specialized. This approach is generally meant by the English term used to designate the object of study, viz., 'Language for Specific Purposes.' The concept centrally behind this term is closely connected to language teaching for professional purposes, where speakers of, e.g., English as a foreign or second language have to learn (additionally) how to use language in areas where they are going to work. In other words, scholars tending to this pole concentrate upon the specific linguistic differences between language used in different settings.
- The other pole is more closely connected to the concept of specialized meaning. The center of this pole is the concept meant by the German term *Fachsprache*, i.e., domain or subject specific language. This concept lays more weight upon the specialized meanings constituting a domain and upon the relations between these meanings and the linguistic choices conventionally made by the agents of the domain. In other words, the view of the scholars tending to this pole is more global, they are rather looking at the language of a domain as a general reflex of the domain and the specialized meanings constituting the domain. This latter view is more discourse oriented in its approach to its object.

The two poles describe two original, fairly different approaches to this object: the first mentioned approach, concentrating upon text production in specialized situational settings, is connected to language teaching, especially to teaching a foreign or second language in connection with vocational training, university studies, etc. A major interest in this approach is to create knowledge about the specific needs to be covered in such specialized language classrooms, in order to make this kind of language teaching as efficient as possible. The study of domain specific language use comes in handy as a linguistic basis for such specialized courses. This kind of language teaching is mostly connected to learning English. For one thing, this occurrence is due to the fact that a number of countries with multiple national

languages (often former British colonies like India or Malaysia) use or have until recently used English as a common language, for example, in administrative and judicial settings. Here, there is a strong need for specialized teaching. Secondly, the position English has especially in the scientific world as *the* lingua franca of international contacts and publications means that there is a strong everyday need among students and scholars from all over the world to acquire specific and specialized English language skills. Consequently, this approach has been followed mainly by scholars working in the field of teaching English to adults with specialized professional or academic needs. Due to the distribution of English in the world described above, the approach is not limited to Britain or the United States, but is widely spread in all parts of the world, although predominantly connected to the teaching of English.

The second mentioned approach, the one focusing more on the specialized meanings, has a different root. It grew out of a general interest in sociology and dialectology and was an extension of former studies of different population groups' ways of living through studies of their discourse. Thus, the original interest was wider in its scope. This study lead to an early interest in global models of communication in specialized settings, combining text internal and text external factors in the descriptions and focusing upon global explanations including and combining discoursal features, relevant knowledge, and social backgrounds rather than just finding specialized elements of the discourse. Germany and Austria were the two countries where this kind of study of specialized discourse was first developed, but also the Scandinavian countries have a tradition for investigating specialized discourse from this perspective.

It is important to say that modern LSP research is normally not placed at any one of the two poles, but rather at some place on the continuum between them. And furthermore there is no 1:1 relation between countries and approaches. Just as an example, recent work by Bazerman (1995) and by Swales (1998) is highly discourse analytic in its approach and thus more broadly interested in global features of the specialized discourse.

Basic Distinctions: Relations between Communicators

In their essence, all approaches to the study of domain related discourse are sociological in their basic assumptions. This tenet is reflected in the fact that degree of specialization of a text and, connected to that, the relation between senders and receivers in a communicative situation concerning their respective levels of expertise is traditionally seen as a crucial factor when setting up models for describing specialized communication. The basic assumption lying behind such models is that the characteristics of the participants in the communication and the purposes pursued by them are main determiners of the way texts are written. Many different stratified classifications of the relevant communicative settings have been proposed. The following tripartite stratification gives a fairly good overall picture of the factors underlying the different proposals:

- Scientific discourse: This kind of specialized discourse is characterized by the fact that both senders and receivers are experts (expert–to–expert–communication). Texts show a high degree of abstraction and a considerable amount of often standardized terminology. These characteristics are seen as consequences of the purpose of communication in such settings, viz., to develop and refine the general knowledge of a domain. Furthermore, the high prestige connected to such discourse and its highly public character means that, apart from aspects of necessary precision, stylistic features play a very important role.
- Practically oriented discourse: Here, too, we find communication where both senders and receivers are experts (expert–to–expert–communication). But in this type of discourse, the experts are not working on developing or refining the general scientific knowledge of a domain. Instead, they are solving practical problems in their daily work and use communicative devices relevant for these purposes. As an example, the difference between the two levels in the stratification is the difference between chemical scientists writing learned articles for scientific journals and chemical scientists working in the laboratory, running their experiments and collecting the data. In the first setting, the purpose is to textually present and develop new knowledge in the field in a public environment (scientific discourse); in the second setting, the purpose of the communication is to solve practical problems occurring in the daily work (practically oriented discourse). The second setting tends to be more informal and to show only the degree of, e.g., terminological specialization in its oral or written texts that is necessary for coping. Aspects of necessary precision play a major role here, although also in this stratum the sociological aspect of showing by way of the applied language that the communicative party belongs to the relevant peer group should not be neglected.
- Discourse of popular science and domain-oriented didactics: The sender-receiver relations are here always asymmetric (i.e., sender has a higher degree of relevant knowledge than the receiver(s)).

Two prototypical cases are communication between experts and consumers (e.g., in manuals) and between experts and novices (e.g., in textbooks). The purpose of this kind of communication is to convey structured knowledge of the domain to receivers who lack this knowledge, but need it for (often) practical purposes. A third prototypical case is the communication of domain-specific knowledge in magazines for popular science. This kind of communication is slightly different from the two cases first mentioned, as it is characterized by a very important element of entertainment, whereas, e.g., manuals and textbooks are more directed toward actually enhancing the receivers' knowledge in practically relevant areas. Although texts of all three prototypical kinds show lots of similarities due to the fact that sender-receiver relations are always asymmetric, they also show important differences, mainly due to the last-mentioned difference.

Traditional Approaches

In order to describe the very complex object of study, that is text from specialized domains in all their aspects, LSP linguistics has included a wide variety of disciplines and approaches from the general toolbox of linguists, see Figure 1.

In the following list, we outline some of the central approaches of LSP linguistics and relate them to the above model.

- Terminology and lexicography: A very central area of LSP linguistics and historically the first area of studies of special domain language to be developed in large scale is terminology. Traditionally, terminology has concentrated upon standardizing the use of words (lexis) and the denomination of concepts, in order to shape languages for specific purposes, so that they are optimal for scientific or professional communication. Recently, terminology has expanded toward other areas like organization, representation and handling of information and knowledge, thus contributing to the development of systems and databases for storing knowledge. Consequently, the interface between knowledge stored in words and knowledge stored in other semiotic systems is of major importance for modern terminological research. Especially technical domains have been the object of terminological studies. Another area connected to lexis and to the manageable representation of words and meanings from specialized discourse is lexicography. The main purpose of this branch of LSP linguistics is to create a sound basis for the production of specialist dictionaries that are highly functional for dictionary users. Consequently, research in this area concentrates on the user and his/her needs and the functions of dictionaries that may be deducted from such studies. Studies from this perspective have been performed in many domains, among them especially the areas of science, law, and administration, where there is a substantial need for translational tools. Finally, it is relevant to mention that research in these fields have treated in some detail the question of the importance of cultural context for the term systems of a domain. A general distinction is made between culture-dependent and culture-independent domains. A prototypical example of a culture-dependent domain is the domain of law. Term systems in

Figure 1 Linguistic disciplines with special importance for LSP linguistics.

this kind of domain are basically different across national cultures, as each nation has developed their own legal system. Consequently, legal terms from different cultures in principle do not mean the same (at least as long as no standardization has taken place). A prototypical example of a culture-independent domain is the field of electricity. In this domain, the degree of overlap between term systems from different national cultures is very much higher than in the culture-dependent domains.

- Intercultural analyses (genre analysis, register analysis, conversational analysis): The wish to develop LSP linguistics toward a more global description of discourse in specialized settings led directly to a focusing on the text as the central object of study. And in this connection, the concepts of genre and of registers have acquired paramount importance. This emphasis is due to the fact that both concepts as descriptive tools are highly oriented toward describing the influence of communicative purposes (genre) and situational settings (genre, register) on texts. Thus, to a large extent, the development of genre and register linguistics has been driven by the interest in developing descriptive tools for LSP research. Concrete studies have concentrated upon conventional characteristics of domain specific genres like research articles, legal judgments, statutes, company brochures, or scientific journals. Especially in a continental European context such studies have been performed as contrastive text and genre analyses across different cultures, thus generating results with special relevance for translators of these specialized genres. Domains with special interest have been the areas of law, medicine, and areas of (technical) science. An area where much work was produced especially in the 1990s was the area of scientific communication, and the applied perspective was the intercultural. This stress was, to a large degree, due to the fact that in these years the development toward English as lingua franca in scientific contexts was speeded up decisively. This development made it especially interesting to investigate whether in scientific contexts the national culture or the (international) discipline is the most influential concerning textual and stylistic choices in text production. An intermediary position was defended by scholars, claiming that academic writing is not influenced by national styles as such, but that it is possible to isolate four different styles, connected to different scientific cultures. No decisive evidence has been found for any of the positions, but the discussion showed different influences at different textual levels. And recently the instruments developed for this type of intercultural pragmatic studies of texts are used also in projects investigating the influence of English textual conventions on texts from different domains (like business communication) originally written in other languages. The intercultural perspective is also relevant for oral communication and has especially been investigated using conversational analysis in a number of cases. The question of differences in ways of negotiating, of showing disagreement, or in solving problems in professional settings has attracted special interest. Finally, it is important to state, that the criterion 'culture-dependent vs. culture-independent domain' is hardly relevant in this perspective, as opposed to what we saw when looking at the perspectives of terminology and lexicography: Also genres from culture-independent domains may differ considerably across national cultures.
- Asymmetric communication: As mentioned above, asymmetric discourse (i.e., communicative situations in which sender and receiver have different levels of knowledge concerning the domain of the communication) is an important part of the object of study of LSP linguistics. And this part of the object has been intensely investigated over the last 20–30 years, applying especially research instruments from text and genre linguistics, pragmatics and cognitive science, but also some instruments from anthropology, like conversational analysis. Studies are geographically concentrated around Europe and North America. The reason could be that the problem of asymmetry in knowledge relations and consequently in (abusable) power relations has been a central issue in the general discussion in these Western societies. Frequent objects of study have been doctor-patient communication, and communication in court and in other administrative settings, but also the area of technical writing (writing efficient technical documents). Research in this area has had a strong element of prescription, of not just registering characteristics of the object of study, but explicitly of contributing to better and more equal communication also in asymmetric settings.
- Studies of Business Communication: The way we have described the object of study of LSP linguistics until now, focus has been on communicative settings that are characterized mainly by their topic, by the object of communication. However, a specific branch of LSP linguistics defines its object of study more on the basis of situational elements and on the basis of the actions performed in specific texts, viz., the study of Business Communication. What makes this discourse domain specific is the fact that it is always tightly connected to the professional purposes of companies or organizations, including such areas as marketing and public relations. Typical objects of study are the internal and the external business communication within and between companies and the

management of these communicative processes. In this connection, instruments from cultural science are often applied in order to describe differences and similarities between senders and receivers from different national or international cultures. And as multimodality plays a major role in texts from these areas of communication, also the instruments from semiotics have been included and used for analyses within this sub discipline of LSP linguistics.

Recent Trends for the Development of the Discipline

In these years the recent trend in the discipline is that three areas are gradually coming into focus, thus supplementing or strengthening (some of) the perspectives and approaches already described above: cognition, semiotics, and the area of document design. The latter areas are already represented in the discipline as it looks today (cf. above), but it is likely that they will receive more attention in the future. Multi-modality is becoming a characteristic feature not only of texts from business communication, but also of texts from many other fields of specialized communication, as the importance of different media and the requirements concerning layout and entertainment are growing. So semiotics will become a necessary perspective when investigating such texts, too. And document design (connected, among other things, to the area of technical writing) has also a good future in a world, in which the amount of information is immense and the time to be allocated for reading limited. The prescriptive tradition of technical writing, intending to judge the efficiency of texts and not just collect data about the text and its coming to life, will gradually gain more importance also in fields where it has not yet been introduced, like in the areas of legal and administrative communication. And finally, there is a growing interest within the field of terminology as well as within other subfields of the discipline to focus not only upon textual or linguistic issues, but to pay more attention to the cognitive activities underlying communication in specialized settings. The expansion requires the inclusion of more instruments from the area of empirical cognitive linguistics, but is just a consequential next step in a development already running. An interesting consequence of paying more attention to this subject is that it may shift focus from superindividual aspects of communication like conventions, group language, etc. (i.e., more sociologically oriented aspects) to individual aspects like personal knowledge resources, mental processes, and learning styles. Thus, where the two prospective trends mentioned first constitute merely a profiling of the discipline within the directions in which it has been developing for the last 20 years, this last mentioned shift of attention may lead to a major paradigm shift in the discipline.

Languages for Specific Purposes: Pedagogy

A Johns

This article is reproduced from the Concise Encyclopedia of Pragmatics, pp. 474–480, © 1998, Elsevier Ltd.

The principal tenet of specific purposes language teaching (LSP) is that of 'specificity': each pedagogical situation and each group of learners is considered to be new and different. Ideally, a unique curriculum and collection of classroom activities is designed for each group of students and teachers in every new context. No single approach, no new or old orthodoxy, is appropriate for all pedagogical situations. Thus, central to LSP pedagogy must be the determination of the unique characteristics of each teaching/learning situation, and the exploitation of these characteristics for development of syllabuses, of classroom activities, and of evaluation and assessment.

Good LSP curricula and teaching require skills, research techniques and sensitivities that are not necessarily characteristic of 'general' language classrooms; for in LSP, the authentic world must be brought to the students, and they must learn to interact with the language as it is spoken and written in target situations. Thus, LSP teachers and curriculum designers are much more accountable than 'general' language teachers. They must be more flexible and willing to negotiate with both experts in the target situation and with the students, who are often quite familiar with the target language situation.

Specific Features of Pedagogical Contexts

Several aspects of the 'specificity' focus required in LSP are critical to curriculum development and pedagogy. First is the role of the target language in the situation in which it will be taught, i.e., the sociolinguistic context. The broadest interpretation of this principle is that an LSP course in a foreign language situation will have to be taught differently from one in a second language situation. English for Academic Purposes (EAP) in China, for example, will have considerably different objectives and classroom activities than EAP in the United States, UK, or another English-speaking country. LSPS also differ in terms of client populations and target-language features. Immigrant workers in second language situations often study the languages of the workplace (also called 'vocational languages'). In a foreign-language context, LSPS tend to be concentrated in academic or international areas, the latter of which include professional languages for negotiation and trade and the languages of the air and sea.

Related considerations include the history and politics of a target language in a pedagogical context. In North Africa, for example, the history of the competition between French and English and the political

The principal tenet of specific purposes language teaching (LSP) is that of 'specificity': each pedagogical situation and each group of learners is considered to be new and different. Ideally, a unique curriculum and collection of classroom activities is designed for each group of students and teachers in every new context. No single approach, no new or old orthodoxy, is appropriate for all pedagogical situations. Thus, central to LSP pedagogy must be the determination of the unique characteristics of each teaching/learning situation, and the exploitation of these characteristics for development of syllabuses, of classroom activities, and of evaluation and assessment.

Good LSP curricula and teaching require skills, research techniques and sensitivities that are not necessarily characteristic of 'general' language classrooms; for in LSP, the authentic world must be brought to the students, and they must learn to interact with the language as it is spoken and written in target situations. Thus, LSP teachers and curriculum designers are much more accountable than 'general' language teachers. They must be more flexible and willing to negotiate with both experts in the target situation and with the students, who are often quite familiar with the target language situation.

Specific Features of Pedagogical Contexts

Several aspects of the 'specificity' focus required in LSP are critical to curriculum development and pedagogy. First is the role of the target language in the situation in which it will be taught, i.e., the sociolinguistic context. The broadest interpretation of this principle is that an LSP course in a foreign language situation will have to be taught differently from one in a second language situation. English for Academic Purposes (EAP) in China, for example, will have considerably different objectives and classroom activities than EAP in the United States, UK, or another English-speaking country. LSPS also differ in terms of client populations and target-language features. Immigrant workers in second language situations often study the languages of the workplace (also called 'vocational languages'). In a foreign-language context, LSPS tend to be concentrated in academic or international areas, the latter of which include professional languages for negotiation and trade and the languages of the air and sea.

Related considerations include the history and politics of a target language in a pedagogical context. In North Africa, for example, the history of the competition between French and English and the political

implications for studying each language influence LSP situations in public secondary schools and universities. Since most languages of wider communication have been the tongues of colonial powers or of privileged classes, the LSP curriculum is often considered to be political and is often scrutinized for cultural and political content by government officials.

The nature of the students within a specified context is also a prime consideration. Their proficiencies and their experiences with the target language as well as their first language experiences and backgrounds are central to educational planning. For instance, professionals in business, engineering and the sciences already conversant with the languages of their professions in L1 should experience a considerably different curriculum from beginning students whose understanding of domain-specific language is limited. Students who can read and write proficiently in their first languages will be enrolled in courses quite unlike those for students who are semiilliterate.

Students and professionals enter an LSP program with theories of how language is learned, e.g., including memorization, reading aloud, or drilling. These theories must also be considered in the development of teaching plans. Related to the learners' theories of language learning are their perceptions of the student/teacher role relationship. Some learners feel that the teacher is 'the boss' and should therefore be in sole control when it comes to determining what should be taught and how it should be presented. Other learners are comfortable with more consultative classroom organization, such as that found in collaborative learning, Whole Language Teaching and many communicative teaching environments.

There is a long history in LSP of examining students' needs and expectations; these are central considerations in LSP curriculum development. They can be divided into three categories: cultural–educational, personal and individual, and academic/occupational. Some LSP practitioners argue that the personal and individual factors should be the primary focus of LSP teaching, that one must start with students' present needs and interests, taking into account their anxieties and differences in learning styles, and emphasizing the pedagogical appropriateness of activities for specified learners. Others argue that with professionals and advanced academic students, in particular, academic and occupational goals, often long-term, should be the primary considerations.

Additional concerns entail the preparation, theories and proficiencies of teachers within a given pedagogical context. Teachers who have been educated in linguistics or language teaching pedagogy are often able to cope with a syllabus that is much more demanding than teachers who have been prepared in literature or another field – or who have had little preparation. Many teachers, especially in a foreign-language context, follow a single theory of language teaching such as Grammar–Translation or 'intensive reading.' Others have heard about certain methodologies and practices such as 'communicative language teaching,' but do not understand the principles and theories on which these approaches are based. Plans for LSP teaching curricula must consider teachers' backgrounds and theories; otherwise, the teachers may attempt to defeat the purposes of the curriculum designers.

In addition, there are many LSP teachers in the world whose proficiency in the target language is quite limited. Again, the choice of syllabus and language activities will have to be adapted for the language skills of the teachers, as well as for the students in the program.

Like students, teachers have visions of student/teacher role relationships. They, too, can believe that teachers are obligated to take the sole responsibility for classroom decision-making and learning. For these reasons, teachers must be an integral part of LSP curriculum development and training. If they do not accept the aims of a more learner-centered LSP program, for example, there may be conflicts between curriculum design intentions and classroom outcomes.

Another issue regarding teacher preparation and attitudes is unique to LSP: because all LSP teaching targets specific purposes settings and languages, many teachers are uncomfortable with their teaching assignments. In English for Specific Purposes (ESP), for example, the majority of the curricula deal with science and technology; however, most ESP (and LSP) teachers have been educated in the humanities. Some experts believe that the teachers' fears can be overcome when they realize that their job is to teach about language and not about content. However, others are concerned that teachers who do not understand the concepts, methods and aims of the specific purpose community (for example, of science) may become estranged and return to what they know, for example, the teaching of 'general' English from an easy-to-follow textbook.

Besides taking the various actors (i.e., teachers, students, politicians) within the pedagogical context into account, the LSP curriculum designers and instructors must study the nature of the oral and written language for which students are being prepared, and the role of the discourse identified in the sociocultural contexts in which students will be working or studying. Here, authenticity is the key to appropriate LSP pedagogy. There are differences of opinion as to the meaning of authenticity; however, in much of the world, the term refers to real, unmodified oral and

written discourse taken from the context in which students will be using the target language. In order to understand the authentic nature of discourses, or genres, pedagogies must link the language produced with the communities in which it functions. The real-world role of a text or discourse and its purpose and audience must be integral to an understanding of LSP curricula.

Because of the specificity of LSP teaching, new curricula and approaches must be constantly developed. Thus, good LSP pedagogy varies widely from country to country, from professional and occupational to academic life, and, within a specific area, from school to school and class to class. However, no approach can be isolated from other language teaching or from second language acquisition research. It must be acknowledged that there are trends in LSP teaching, influenced principally by 'general' teaching methodologies, by technology, and by language processing and learning theories. It will be the purpose of the remainder of this discussion to identify and discuss some of these trends.

Current Trends

Learner-Centered Approaches

As was mentioned previously, attention to the nature of learners is central to modern LSP teaching, as it is to much of 'general' language instruction. In its most extreme form, a learner-centered approach is based upon the principle that learning is totally determined by the nature and will of the students (Hutchinson and Waters, 1987). When discussing learner-centered pedagogies, it is essential to examine the issues of learner prior knowledge, language processing, and conceptions of tasks that influence classroom practices.

Exploiting learners' prior knowledge and experience is central to an understanding of a learner-centered pedagogy. Work in schema theory, based upon the connectionist view of language acquisition, has assisted teachers in developing pedagogies that draw upon students' knowledge of the content of the lesson (content schemata) and of the structure of the authentic discourses (formal schemata) (Carrell, 1983). When preparing for a language activity, students are given questions and activities that draw upon their often extensive first language schemata and experiences with the world, thus motivating interest and promoting familiarity with the demands of the task.

Learners also come to the classroom with specific styles for approaching learning, i.e., "cognitive, affective and physiological traits that are relatively stable indicators of how learners perceive, interact with and respond to the learning environment" (Reid, 1987: 87). Some researchers focus upon perceptual styles or learning channels: the visual, auditory, kinesthetic and tactile. Others are interested in ability to deal with ambiguity, noting that learners may be convergent, i.e., seeking closure or resolution (a style encouraged by math and sciences) or divergent, those who enjoy evaluation, criticism, and problem-solving (often students from the humanities and social sciences). Learners also have preferences for classroom organization, e.g., many of the learners in LSP contexts are field-independent, i.e., they would prefer to complete a project alone rather than in a group. In addition to styles, strategies for completing tasks are considered in a learner-centered curriculum. One of the most complete and well-developed systems of strategies appears in publications by Chamot and O'Malley (1986: 17). In their scheme, strategies can be divided into these categories:

> Metacognitive strategies: including executive processes for learning, monitoring one's comprehension and production, and evaluating how one has achieved an objective.
>
> Cognitive strategies, in which the learner interacts with the material to be learned by manipulating it mentally or physically.
>
> Social–affective strategies, in which the learner either interacts with another person in order to assist learning, or uses some kind of affective control to assist learning.

Closely related to the issue of strategies is that of language processing. From the 1980s, interest in the relationship between first and second language processing has grown, both in reading and in writing. Of particular interest are the studies of process transfer by second-language writers in specific purpose situations. For example, St John (1987) discovered that Spanish scientists writing in English were able to draw extensively from their prior knowledge of content and research article form. They were therefore able to concentrate upon their principal concerns: precise language and the development of specific article sections. These and others' insights into the processing of written texts have led to curricula that prepare LSP students for reading and writing by assisting them in activating the appropriate schemata, in drafting texts and revising, and in helping them to consider audience and purpose as they comprehend and produce text.

In learner-centered approaches, course design and teaching often become negotiated, dynamic processes, since needs, expectations, and student resources vary with each group and within a single course sequence. This does not mean that students are in total

control, by any means. However, it does suggest that LSP teachers must take into account student learning styles, strategies and language processing approaches. And, since research indicates that students benefit from expanding their strategies repertoire and from developing a metacognitive awareness of their text processing, LSP teachers should assist students in becoming more flexible and more aware of their own learning styles and approaches.

Genre-Based Approaches

Whereas some curricula begin with the nature of the learners and are designed to expand upon learner strategies and metacognition, others are sensitive to the discourse community in which the learners will be functioning, e.g., an international business, an academic department, a tourist agency, or a factory. In these genre-based curricula, the discourses from the target speech community are studied, preferably by the students themselves, in terms of text roles in the target context; for the structure, styles and purposes of discourses are defined by the communities in which they operate (see Swales, 1990).

A discourse community is a group of likeminded people with common goals and shared ways of looking at the world. Members communicate with one another through a variety of genres that serve the community's purposes, e.g., faxes, e-mail, newsletters, research articles, reports, and memos. Though discourse communities may produce the majority of genres in a single language (e.g., English) in many of the sciences, members may share values and aims that are realized in a number of different languages.

In genre-based approaches, students are immediately exposed to exemplars of genres written in the target language from within identified discourse communities. Through instruction or induction, students identify the purposes, macrostructures and linguistic features of these genres and relate their findings to the purposes of the genres within the discourse communities.

How is this done in classroom practice? One example may suffice. In academic purposes settings, students (or teachers) can act as ethnographers, interviewing experts and collecting realia from the target setting. If the community is a group of international agronomists, for example, students interview practicing agronomists to identify those genres that are central to the community, e.g., academic articles, dissertations, and newsletters. They compare various exemplars for a number of elements, e.g., macrostructure, grammar, lexicon, and metadiscoursal features. The discourses they have analyzed then become the texts for the LSP class, as students attempt to produce their own versions and to compare them with the texts by experts. Thus, in a genre-based class, the sequence of activities is (a) expert interviews, (b) collection of genres, (c) genre analysis, (d) preliminary conclusions about genres' purposes and features, (e) student genre production, and (f) evaluation by experts.

Task-Based Approaches

'Task' is – and probably will remain – ill-defined in the literature, yet the concept has become increasingly important to LSP, for it meets criterial demands and can be suitable for either a learner-centered or a genre-based approach. In learner-centered curricula, tasks are seen either as learner actions or as learner representations of tasks. 'Doing' or action tasks are related in a manner much like the behavioral objectives of the 1950s: 'Learners will use Wh-questions in controlled drills,' or 'Learners will identify the main points of a text.' Though dated, these 'doing' tasks continue to provide structure and guidance for many curricula. A more current expansion on the 'doing' concept comes from the Notional–Functional language teaching advocates. For them, 'doing' can be divided into three categories: an action sequence, a notional–functional description, and a list of teaching points. An action sequence might be 'A person arrives at a party'; the description, 'Meeting strangers, introductions, first names,' and the teaching points would be "I'm Mohamed. She's Maria. I would like you to meet my wife" (Corbel, 1985: 78).

A learner-centered task definition of the early 1990s, 'task representation,' originates in the writing process literature. In this realization, the manner in which the learners mentally represent a task which they are given is central to learner success or failure. Thus, if learners misconstrue the audience or context for a writing task, they will find it difficult to produce an acceptable written product. Likewise, if the learners misread a text because their mental representation is not consistent with that of the text writer, their comprehension will not be complete.

Others speak of abilities rather than actions as central to task completion. They list as objectives phrases such as the following: 'Students will develop the ability to assimilate new concepts and information associated with a specific subject,' 'They will be able to use linguistic resources to perform *x* task,' or 'They will understand particular modes of inquiry within a community.'

As can be seen from the last of the two definitions discussed, 'task' has become an important term both to learner processing studies and to understanding the demands of the target discourse community and its

genres. Doyle (1979) has developed an appealing, global definition to guide pedagogues:

> The term 'task' focuses attention on three aspects of students' work: (a) the products (or genres) students are to formulate, (b) the operations that are to be used to generate the product, i.e., the process, and (c) and the givens, the resources available to students in accomplishing the tasks (Doyle, 1979: 163).

These are some of the definitions of task that are influencing LSP teaching and curriculum development. Because of the plethora of definitions and because there is no agreement upon task difficulty or breakdown of tasks into mini-moves, introducing and sequencing of tasks in a curriculum is problematic. Nonetheless, task-based approaches, considered more authentic and holistic than national/functional or other alternatives, have been embraced by key figures in the LSP movement.

Technological Influences

New definitions of literacy have begun to appear in the literature which will have a major impact in the twenty-first century upon the understanding of LSP teachers' roles and instructional aims. The computer is both widely available and can be used for many different purposes, including word processing. Because of this, it has become a necessary literacy tool in the lives of many LSP students, whatever their academic or professional/vocational goals. Thus, computer literacy, involving word processing and, in some cases, programming, is a fundamental aim in many LSP courses. Car mechanics must not only find the mechanical problems, but they must input the exact terms to cue an appropriate output. Businesspeople must read and exploit printouts, access bulletin boards, and make use of networks to communicate with their colleagues worldwide.

The technological demands of LSP settings include as basic a skill as typing and advanced skills in communication and programming. To meet these demands adequately, many LSP settings are computer labs in which students network to collaborate or peer review their writing, or use the computers to communicate with members of worldwide discourse communities.

Evaluation of Curriculum and Teaching

In LSP, evaluation leads to change. The inadequate LSP curriculum is one that is overwritten or inflexible; the appropriate curriculum provides for change and input by all of those involved in its success. Because the curriculum must be specific to students' needs and their target discourse communities, teachers and students continually review the goals and purposes of their courses. Students are given opportunities to reflect upon the value of a particular classroom activity or text, in terms of their own learning styles and processes and their understanding of program goals. They can be asked, for example, whether they understood the purposes of what was being taught, whether they already know how to do an activity, whether an activity provided appropriate variety or focus, whether it assisted them in gaining understanding of the tasks they must perform, and whether they believe that they could transfer the task or use the texts in real world settings.

Teachers can also keep reflective evaluations, journals of what went well and what did not. They might ask themselves some of the following questions as they are involved in curricular revision: 'Were the needs assessments accurate and complete?' 'Were the needs assessments accurate and complete?' What do we still need to find out about students or about the target community?' 'Are the materials, methods, and activities appropriate to the newest assessment of student needs?' 'What changes should be made?' 'Are resources for teachers and students appropriate?' 'Where can we get additional resources?' 'Are learner strategies adequate?' 'What alternative strategies should we be encouraging?' 'Do learners attend regularly, apply themselves, and practice outside of class?' 'If not, why not?'

Student Assessment

Student assessment is another issue that is central to the success of a curriculum, especially in ESP programs, which are highly accountable. Though testing is an area of LSP that has been generally neglected, much can be done to demonstrate student abilities and knowledge. One important area of assessment, especially in learner-centered curricula, is of self. Several types of self-assessment measures are suggested in the literature, depending upon the goals of the assessment process. There are, for example, selfassessments of writing or reading, in which students are asked to reflect upon the success of their approaches to particular texts. There are attitude and motivational assessments as well. Peer assessment is also central to the learning process; students can be asked to consider criteria for discourses, then to evaluate the written or spoken work of their colleagues.

More traditional tests are for placement, proficiency and achievement, all of which are somewhat suspect within the LSP community. There are a number of reasons for these suspicions, the principal ones

being that it is very difficult to test students on the real-world tasks that they will be performing in discourse communities for these tasks are very complex and task-graders are generally not target community experts. Nonetheless, tests do exist, principally because it is necessary to demonstrate student progress to clients and administrators. Perhaps the best-known and most universal LSP examinations are for English: the American TOEFL which is designed to predict general academic success, and the British Council ELTS modular test, in which various forms are available for students in a number of academic disciplines (e.g., physical, social, medical sciences).

Because specific purpose language teaching requires specific purpose testing, however, the best assessments take place at the local level. One promising area of assessment comes from the Portfolio Movement, an important contribution to the teaching of writing. Student portfolios, developed over time, contain student- and teacher-selected exemplars of work that is central to course objectives. Throughout the course, students reflect upon their portfolio entries, another method for self-assessment and evaluation of growth. One example of portfolio for general academic purposes students is this: through questionnaires and interviews with subject specialists, students and faculty determine the generic tasks that appear to cross disciplines and therefore to be required in some form by all the faculty, e.g., evaluative summaries, note-taking, critical responses to readings, and analysis of data. Then throughout the LSP course, students complete these tasks and select and reflect upon task examples in their portfolios. Teachers evaluate these tasks using specific, task-based criteria. When the term is over, the students have evidence for the academic faculty of their ability to perform the generic tasks assigned.

Conclusion

Hutchinson and Waters, in their influential work (1987), speak of ESP (and LSP) as chance-taking approaches, the 'Wild West of ELT.' They also claim that LSP is the most demanding of language-teaching experiences for everyone involved. Because there are no orthodoxies as guides, teachers are faced with evolving curricular challenges. Because the teacher is obligated to prepare the students for the real world, there are new realms of knowledge and skills that must be dealt with and individuals from target discourse communities (e.g., subject specialists) who must be consulted.

Though this article has touched upon some current trends in LSP, there are many LSP courses throughout the world that do not reflect these trends. In many foreign language settings, such as in China and Japan and in parts of Latin America, there continues to be a strong emphasis upon analysis of microfeatures of texts without concern for the discourse communities in which the texts are written. Pedagogies result that are more typical of the 1960s than of the late 20th century (Swales, 1985). In many parts of the world, learner-centered methodologies are not deemed appropriate, either by the political/educational leadership or by the students. Though the understanding of technology is vital in many areas of the developed world (e.g., in the European Community), its use has barely touched other regions. In some learning contexts, subject or professional specialists are easily accessible. In others, teachers with an LSP mandate are working in relative isolation.

Nonetheless, the ideal of LSP remains: a pedagogy must consider student styles, strategies, expectations and needs seriously. It must consider, as well, the target language use contexts, in order to develop a syllabus and teaching practices that are specific to a new learning situation.

Languages of Wider Communication

J Brutt-Griffler, State University of New York, Buffalo, NY, USA

Languages used to facilitate cross-linguistic communication among speakers of different languages brought together by processes of migration, trade, or travel, stretch back to the beginnings of recorded history. Some had extensive reach – covering much of the world then tied together by existing trade routes, such as the Silk Road, a loose network that linked the Mediterranean and East Asia – such as Soghdian (a language still spoken in present-day Tajikistan), and, at a later date, Persian (Foltz, 2000). But no language down to the past century could claim large numbers of speakers across the globe. For instance, while Latin served as a lingua franca in Europe for centuries, it had effectively no presence throughout Asia and Africa. One of the hallmarks of the most recent stage of *globalization* has been that the development of such a world language has become for the first time a possibility, and that English appears to have already attained that status or to be well on the way to doing so. Perhaps because the phenomenon is so comparatively new, while languages serving large expanses that formerly made up large segments of the world market, such as Persian or Latin, have been around so long, terms such as *world language* and *international language* – even at times *language of wider communication* – have tended to be employed, if not exactly interchangeably, then without clear demarcation. In their precise meanings, a *world language* must by its nature encompass the entire globe, while a language can be said to be *international* if it serves clusters of nations. For its part, a *language of wider communication* signifies one that provides a mutually intelligible medium for speakers in multilingual societies.

World Language

A *world language* is not simply the most widely spoken language in the world, or the one that is the official language in the greatest number of nations. To merit such classification, a language must have achieved a position of global preeminence in another key respect: its existence must have become a practical necessity to fill a wide range of functions brought to the fore by processes of globalization. The development of world language, then, does not represent the culmination of a linguistic process at all; it comes into being as the concomitant of larger historical trajectories, powerful forces that condition communication needs around the world. For most of the history of the world, there has been only the most remote contact between peoples in distant parts of the world. While a world market loosely existed from ancient times, the limitations of transportation and communication technology determined supranational regional zones as the largest effective units for which a lingua franca such as Persian, Arabic, or Chinese constituted a practical necessity. The need for a world language is not felt so long as communication is largely limited to bilateral relations between nations or take place in regional settings in which a particular international language such as Arabic or Spanish suits the purpose. World language requires a

Languages used to facilitate cross-linguistic communication among speakers of different languages brought together by processes of migration, trade, or travel, stretch back to the beginnings of recorded history. Some had extensive reach – covering much of the world then tied together by existing trade routes, such as the Silk Road, a loose network that linked the Mediterranean and East Asia – such as Soghdian (a language still spoken in present-day Tajikistan), and, at a later date, Persian (Foltz, 2000). But no language down to the past century could claim large numbers of speakers across the globe. For instance, while Latin served as a lingua franca in Europe for centuries, it had effectively no presence throughout Asia and Africa. One of the hallmarks of the most recent stage of *globalization* has been that the development of such a world language has become for the first time a possibility, and that English appears to have already attained that status or to be well on the way to doing so. Perhaps because the phenomenon is so comparatively new, while languages serving large expanses that formerly made up large segments of the world market, such as Persian or Latin, have been around so long, terms such as *world language* and *international language* – even at times *language of wider communication* – have tended to be employed, if not exactly interchangeably, then without clear demarcation. In their precise meanings, a *world language* must by its nature encompass the entire globe, while a language can be said to be *international* if it serves clusters of nations. For its part, a *language of wider communication* signifies one that provides a mutually intelligible medium for speakers in multilingual societies.

World Language

A *world language* is not simply the most widely spoken language in the world, or the one that is the official language in the greatest number of nations. To merit such classification, a language must have achieved a position of global preeminence in another key respect: its existence must have become a practical necessity to fill a wide range of functions brought to the fore by processes of globalization. The development of world language, then, does not represent the culmination of a linguistic process at all; it comes into being as the concomitant of larger historical trajectories, powerful forces that condition communication needs around the world. For most of the history of the world, there has been only the most remote contact between peoples in distant parts of the world. While a world market loosely existed from ancient times, the limitations of transportation and communication technology determined supranational regional zones as the largest effective units for which a lingua franca such as Persian, Arabic, or Chinese constituted a practical necessity. The need for a world language is not felt so long as communication is largely limited to bilateral relations between nations or take place in regional settings in which a particular international language such as Arabic or Spanish suits the purpose. World language requires a

stage at which every point, or virtually every point, in the world is thrown into relation with every other, when global communications has become virtually instantaneous, and the trip from any place in the world to any other has been reduced to hours rather than weeks or months. It requires a structure of world trade that is truly multilateral – rather than one that transports goods and services within definite imperially defined channels only (as was the case during colonialism in Asia and Africa).

Such international relations throw together persons from many nations from diverse regions of the world into regular contact, and make ease of communication among them an economic imperative, requiring a recognized common linguistic medium, a world language (*see* **Intercultural Pragmatics and Communication**). Finding its basis primarily in the economic realm, world language also more and more penetrates technological, scientific, intellectual, political, and even the cultural realm, as the need for translation raises a barrier to the rapidity with which information is disseminated in the digital age. In such a case, the continued spread of a world language finds a strong impetus not only in political economy, as global trade represents an increasing share of the total, but through intellectual and cultural motives, too, as people around the globe are induced to learn it to further their wide-ranging objectives (*see* **Motivation and Attitude in Second Language Learning**).

On the other hand, a world language need not be widely spoken in every nation of the world, nor must most people in the world speak it, any more than earlier regional lingua francas such as Latin in Europe or Persian along the routes of the Silk Road were universally understood in the supranational political geographies they served. Yet, at a minimum, it would be reasonable to expect such a language to be widely spoken on every continent, to have an ever-growing number of speakers in every nation, and to have emerged as the single most important language of global commerce.

The world language would not necessarily have the most mother tongue speakers, a distinction that currently belongs to Chinese, with its 874 million speakers (Grimes, 1996). On the contrary, one of the salient characteristics of a world language, like that of a supranational lingua franca like Latin or Persian in an earlier epoch, is that the majority of its users would be non-mother tongue speakers, bilinguals for whom it represents a second language. For them, a world language serves global, as opposed to purely local, functions. It is an entry-point into global relations, and one that need not usurp or even threaten the entrenched uses of the other language(s) they speak.

Is English a World Language?

Most estimates place the total number of English speakers globally at between 500 million and 1 billion, the difference consisting mainly in how proficiency in the language is defined. The best indication of the status of English as a world language is provided by the number of people around the world who feel compelled to gain at least some knowledge of the language, irrespective of their level of ultimate attainment. For it is the motivation of hundreds of millions across the globe to learn English that gives the measure of the degree to which it has become the world language, there being no comparable phenomenon associated with any other language. The rise of English is also demonstrated by the increasing frequency with which it is being incorporated into school curricula (*see* **Language Policy in Multilingual Educational Contexts**), not only in "second language contexts" (such as India and South Africa) where it serves as a *language of wider communication* on the national scale (see below), but even in foreign language contexts (including China and Europe), though this distinction is somewhat losing its usefulness for the description of English. The entrenchment of English in the school curriculum in diverse societies throughout the world will tend to produce a greater proportion of English users globally over time.

While the nature of a world language seems to preclude the need for more than one, the possibility cannot be ruled out that another language of equal, or even greater importance, could emerge, either joining or replacing English in its position of preeminence. As Graddol (2004) has argued, rapid shifts in demography together with a restructuring of linguistic space by modern telecommunications may produce profound effects on language use by the middle of the 21st century, perhaps redefining how we think of languages (local, national, regional), and simultaneously transforming the notion of world language.

Development of World Language

There have been two primary paradigms employed to account for the linguistic effects of globalization that would give rise to a world language: modernization and linguistic imperialism. Modernization describes the spread of industrial production, technology, finance, and trade, the burgeoning of the middle class, and the birth of a consumer culture, among nations that were previously 'underdeveloped'. From this standpoint, the increasing use of a common language throughout the world simply represents the natural concomitant of the march of progress. In marked contrast, linguistic imperialism

finds in the spread of certain languages to the exclusion of others the exercise of Western, ultimately imperialist, hegemony, the extension into the cultural and linguistic realm of the political and economic control that the 'Center' has exercised over the colonial and neocolonial periphery for centuries. Both explanations take for granted that globalization, including the spread of English, represents an essentially Western-driven process, one of which the rest of the world catches up to or is incorporated into European/North American society, rather than a multi-polar process driven by no central hegemony. Brutt-Griffler (2002) shows, rather, the development of English into or toward the status of a world language to be considerably more complex, a process that includes numerous forces, economic, political, cultural, and intellectual, underlying globalization, combined with the active agency of its new speakers around the globe choosing to learn the language.

World Language and Language Contact

The development of a *world language* – as one spoken primarily by non-mother tongue speakers – should produce effects on the other languages of the world and on the world language itself. As a language of bilinguals, it is thrown into contact with languages throughout the world, leading to processes of language change. Certainly the spread of English has exerted an effect on other languages via language contact. This process ranges from the incorporation of English words into languages as diverse as German and Japanese, to the emergence of mixed varieties of other languages and English, for example, chiHarare, a mixture of Shona and English spoken in Zimbabwe.

At the same time, other languages have in turn exerted an influence on English. For English itself, entering a phase of the history of the language known as the World English phase, in which non-mother tongue speakers have proliferated until, as noted above, they now exceed the number of its mother tongue users, has produced highly noticeable changes. World English – the phase of the history of the language in which it functions as a world language (Brutt-Griffler, 2002) – has spawned *World Englishes*, often called non-native varieties of the language (Kachru, 1986) spoken in nations throughout Africa and Asia (see also World Englishes). It is contested whether there is any global standard of World English, and if so, what that standard might be. But it is clear that the growing number of speakers of new varieties of World Englishes increases their potential to exert a greater impact on international usage of the language.

Linguistic, Political, and Social Consequences of World Language

The implications of the development of a world language have been significant, ranging from concerns over its alleged connection to a loss of linguistic diversity, to questions of access to high-level proficiency in a language that often confers power and privilege to its speakers, to the use of such a language to transcend ethnic identity and traditional gender roles, to questions of the meaningfulness of the paradigm of nativeness within a language of primarily non-mother tongue users (*see* **Identity: Second Language; Nonnative Speaker Teachers**). Though all of these questions are important, none has received the attention that has been devoted to the fear that the global spread of English represents a causal factor in the endangerment of languages. Graddol (2004) notes, "Many believe English will become the world language to the exclusion of all others." It has been strongly suggested that in Africa, for instance, the spread of English "is leading to the top-down displacement of numerous other tongues" (Nettle and Romaine, 2000: 144), a contention that has been challenged by others (Mufwene, 2001, 2002). Indeed, if such were the case, we would expect to find gains in the number of native speakers of English in Africa proportionate to the loss of those of disappearing languages, something the statistics do not appear to support. Rather, as Brutt-Griffler (2002) has argued, the spread of English as a world language produces not monolingual English speakers but bilinguals (see also Bilingualism and Second Language Learning). Graddol (2004) remarks, "English will indeed play a crucial role in shaping the new world linguistic order, but its major impact will be in creating new generations of bilingual and multilingual speakers across the world."

As English is learned in many multilingual contexts at an earlier age and reinforced by exposure gained through various media, new and old (Berns and de Bot, 2004), the distinction between native and non-native speakers of the language may be increasingly blurred, as fluency in it may be used as an 'exit visa' from ethnic identity and traditional gender roles (Mazrui, 2004). The continued growth of English as a world language will prompt ever-greater concerns about access to the language for all members of society, and not simply for those who can afford to buy it, and about the economic and intellectual advantages knowledge of such a world language can confer.

International Language

Though the rapid growth of the world language over the last century has taken attention away from other

international languages, a large number continue to play a vital role in the modern world, as they have for at least past millennia and will continue to do for the foreseeable future. International languages are most typically associated with the facilitating of international communication – a function that in past centuries Latin, Persian, Greek, Sanskrit, Turkish, and French all played – and the linking of diasporas across wide geographical expanses. In the modern world, however, particularly with the emergence of a world language, their primary role seems to be developing into the maintenance of supranational economic, cultural, and, within certain limitations, ethnic zones (set off by the use of, for example, Arabic, Swahili, Chinese, Spanish, Portuguese, or French). In some cases, such as Arabic or German, these represent a lack of correspondence between ethnolinguistic identity and national boundaries, as Arabs are dispersed over more than twenty nations on two continents and German is given official or special status in eight European nations. In other cases, such as French, its existence as an *international language* reflects a colonial legacy, in which most of the thirty-four nations in which French has a special status are former African or Caribbean colonies of France (see Table 1) – nations in which generally most people do not speak French as a mother tongue. A variation of this imperial case is illustrated by languages such as Spanish, which though introduced into the Americas as an imperial language, is now the mother tongue of the majority of people in more than twenty nations in the Americas, which now dominate the Spanish-speaking world. And in yet other cases, such as Swahili, an international language may constitute the expression of emerging postcolonial nationalism that plays out in a supranational context – in this case East Africa. Though Swahili is not originally indigenous to the region and has not been the mother tongue of the vast majority of its peoples, it has at least begun to take on that function for increasing numbers. Another group of international languages, of which the largest is Chinese, are more nearly expressions of a diaspora.

Table 1 Number of nations in which international languages are given some official status

1. English	63
2. French	34
3. Spanish	23
4. Arabic	23*
5. German	8
6. Portuguese	7

Ammon, 1994, p. 1726; *Crystal, 1997a, p. 359.

The categories listed above need not be mutually exclusive. For instance, Portuguese is the official language in five African nations, though it is not for the most part the mother tongue of the majority of the peoples in those nations, and yet, like Spanish in the Americas, has become the mother tongue of the majority of the largest lusophone nation, Brazil. French itself, like German, is spoken in several European nations – as well as by a diaspora population in Canada. Russian has spread to neighboring countries partly as an imperial language learned as a second language by peoples incorporated into the Russian empire and partly via a large Russian-speaking diaspora in those nations. In other cases, like Kurdish, the language can be called international, as it crosses national borders, but only because the Kurds have been denied nationhood by the three more powerful states in whose territory their would-be homeland lies. This also brings out a significant distinction between *international* and *world*, because international is based on the original construction of the *national*, world is not.

Major International Languages: A Statistical Picture

The major international languages can be distinguished through an examination of some key statistics, such as those in Tables 1 to 4, which show the number of nations in which official status is accorded to particular languages (see Table 1), and which show the number of mother tongue speakers (see Table 2), total speakers (see Table 3), and second language speakers of selected languages (see Table 4). Tables 5 through 7 provide proportions of print publications in different languages in the sciences (see Table 5 and Table 6) and humanities (see Table 7) and Table 8 shows the percentage of web pages on the Internet (see Table 8). Statistics by themselves can be revealing, but they only tell part of the story. For example, it

Table 2 Number of mother tongue speakers of 10 languages, in millions

is clear that English has no rival as an international language, strengthening its claim as the world language. French, sometimes said to be a challenger, or a "big language" (Graddol, 1997), clearly does not stand out as having the same importance on a global scale, as shown by its placement as a distant sixth as a language of publishing in Chemistry, the discipline for which the most accurate statistics are available (82.5% for English, 0.5% for French, see Table 5), or fourth and second. Respectively, in the natural sciences (90.7% to 1.3%, Table 6) and the humanities (82.5% to 5.9%, Table 7) as compiled by Ammon (1998). French also ranks only fifth in number of web pages (68.4% to 3.0%, Table 8). And while French is second to English in the number of nations in which it is an officially recognized language (63 to 34, Table 1), when we examine total numbers of second language users (Table 4), we find that French, with some 50 million estimated users, ranks not only behind English (300 million+), but also Chinese (188 million), Indonesian (140 million), Hindi (120 million), and Russian (110 million). While such numbers, however, give a very approximate measure of significance as a *language of wider communication* (see below), it does not necessarily reveal much about a language's international significance. For instance, Indonesian and Hindi are mainly confined to the national borders of Indonesia and India, while French second language speakers lie mainly outside of that nation, as the number of nations in which French serves as an official medium (34) demonstrates, as compared to that of Indonesia and Hindi (1 in each case). Taking the statistics as a whole, however, we can conclude that French is an internationally significant language within the former French colonial world, but, as the statistics on scientific publishing demonstrate, it is not a language commonly chosen when the goal is to reach a world audience.

In the same manner, the contention that German represents a major international language as demonstrated by its official status in 8 nations (Ammon, 1994), placing it behind only English, French, Spanish, and Arabic, and ahead of Portuguese, looks quite different upon further analysis. Because all of those nations lie in a concentrated portion of Europe, and given estimates of only some 28 million second language speakers, it would be more accurate to describe German as a regionally important language in central Europe, of the same type, but not on the same scale, as Arabic (official in 22 nations and with more than twice the number of speakers).

The acceptance of a language as official also reflects neocolonialism in politics that may obscure

Table 7 Percentage of languages used in humanities publications, 1978 to 1995

	1978	*1982*	*1986*	*1990*	*1995*

Ammon, 1998, p. 167.

both actual distributions of language users and their increasing importance globally. For example, while European languages are often official in former colonial settings, other languages do not receive similar endorsement. Thus, while German, though spoken by only 1.5% of the population of Belgium, has official status there, Turkish is not recognized as such in Germany, though its speakers make up 2.4% of the population, and though it is recognized as such in Bulgaria. There are some 15 million Turkish speakers outside of Turkey, not far behind the total of 17.5 million German speakers outside the main German-speaking nations of Germany and Austria.

Functions of International Languages

If we were to conceive the functions of an international language to include linking diasporas to mother countries, most of the world's larger languages could be said to be international in an age of increasing transnational migrations. International languages as such rather serve more institutional functions. They generally confer a sense of political affinity among groups of nations, whether, as in the case of Arab nations and Spanish-speaking American nations, as a sort of proto-nationalism, or, as in the case of France and Belgium and their former colonies, something more along the lines of a sphere of influence with colonial or neocolonial overtones. They may also facilitate the creation of a common market, whether institutionalized or more informal, particularly but by no means exclusively in the area of cultural productions, such as the Spanish-language film and music industry in Latin America. International languages allow global telecommunications giants to beam information in television signals via satellite to large international audiences – as for instance the Arabic station Al-Jazeera. Finally, they facilitate educational ties between nations sharing a common language.

Impact of English as a World Language on the Functions and Usage of International Languages

While international languages retain their importance in linking language groups across national and continental boundaries, they seem to be losing importance where the goal is to communicate with a global audience. There is thus a pronounced trend toward English as the medium for the publication of scientific research (Tables 5, 6, and 7). Table 6 shows that of the articles indexed by *Chemical Abstracts* the percentage in English increased from 62.3% in 1978 to 82.5% in 1998, while the proportion in every other language except Chinese fell. The two languages that followed English in 1978 experienced particularly dramatic declines thereafter, Russian (19.5% to 3.1%) and German (5.0% to 1.6%), while French fell off from 2.4% to just 0.5%. Ammon's (1998) figures (Table 7) demonstrate the same trend the natural sciences as a whole. English shows similar dominance on the Internet (Table 8). In 2000, 68.4% of web pages were in English, with only Japanese (5.9%) and German (5.8%) registering more than 5%, followed by Chinese (3.9%), French (3.0%) and Spanish (2.4%) above the 2% level (Maurais, 2003).

Jacques Maurais, 2003, p. 22.

Languages of Wider Communication

A language of wider communication, also known as a *lingua franca*, provides a mutually intelligible medium for speakers in multilingual societies, to some extent replicating on the intra-national scale the function of world (or international) language(s) on the global scale – although world and international languages are languages of wider communication in the broadest sense of the term. There are three major categories of languages of wider communication:

- international languages which may not be indigenous to the region, such as English, French, or Portuguese in Africa, or alternatively may be indigenous, as in the case of Swahili in East Africa and Hausa in West Africa; English as a language of wider communication in Europe (Seidlhofer and Jenkins, 2003) represents something of an intermediate case, because English is indigenous to a

portion of the region but not in continental Europe where it plays its specific role;

- languages of indigenous origin that have come to fill the role of national (or regional) languages, though they are not the mother tongues of the majority of the people, for example, Bahasa Indonesia (Indonesia), Tagalog (Philippines), or Hindi (parts of India);
- languages of local and recent origin that have arisen at least in part specifically to fill the function of a language of wider communication; often called *urban vernaculars*, they are mixed languages containing elements of local languages, and sometimes international languages such as English or French; Isicamtho (South Africa), chiHarare (Zimbabwe), and Town Bemba (Zambia) number among them.

When English or French functions in this capacity, it tends to be referred to as a *second language*, to signal that it provides many speakers of a given nation with a medium in which to communicate when confronted with nationals outside the speaker's language group. In such cases, the second language may or may not be given official status, but it is generally adopted for a wide range of societal functions: economic, political, and cultural. In the second case, the languages are always official, and are also designated as national, as they are held to embody the national aspirations of the people, as may also be the case with an international language such as Swahili that is indigenous to the region. In the case of *urban vernaculars*, they are seldom given institutional recognition of any kind, and in many cases have only begun to be distinguished as languages in their own right. In the highly fluid circumstances in which they arise, they may even become transformed into the mother tongues of at least a portion of their speakers and may also be making their way into the classroom (Childs, 1997).

When a language is spoken in only one or a few countries as a second language by many of its speakers, that constitutes evidence that it functions as a language of wider communication (*see* **Lingua Francas as Second Languages**). Two such languages are Swahili, which according to some estimates has as few as 5 million mother tongue speakers and 30 million second language users, and Bahasa Indonesia, with some 17 to 30 million native speakers as compared to 140 million non-mother tongue users. Ten major languages of wider communication, with estimates of their number of second language speakers, are given in Table 4.

Functions of Languages of Wider Communication

Languages of wider communication (*lwc*) fill different functions, from the overtly political and institutional characteristic of top-down statist language planning agendas to bottom-up processes that may even go unnoticed by policymakers. When designated as official or national languages, *lwcs* can be used to promote nationalism in multi-ethnic societies, and may be associated with particular political forces or ideological aims – a role that may be as divisive as it is unifying. Hindi in India, for example, is widely associated with Hindu nationalism and viewed with suspicion, if not hostility, by large sections of the population. At the other extreme, the *lwc*s that have arisen in urban African contexts have been the spontaneous products of the mixtures within them of large numbers of speakers of various – and often closely related and mutually intelligible – languages. Closely connected, as Mufwene (2004) has pointed out, to the encroachment of urbanization on "the function of most indigenous languages as markers of ethnic identity," these languages may be used to deemphasize ethnic identity or to signal urban identity. Despite the latter connotation, or perhaps indeed because of it, such mixed languages, including South Africa's Isicamtho, chiHarare in Zimbabwe, Lingala in Congo, Town Bemba in Zambia, and Wolof in Senegal, appear to be spreading apace to rural areas, too. Because they are largely confined to non-elites, such *lwc*s, though probably the fastest-growing languages in many places, have so far received little, if any, official recognition.

Number of Speakers and Genetic Relationship

Lao belongs to the southwestern subgroup of the Tai language family. It is the national language of Laos and the first language of approximately 70% of the population of 5.4 million. There is considerable regional variation in dialects but the Vientiane dialect is regarded as standard Lao and serves as a lingua franca for the country's many ethnic minorities. Lao dialects are spoken by a further 12–15 million people in northeast Thailand, and there are sizeable overseas Lao communities in both France and the United States.

Lao bears many very close similarities to Thai and, because of Thailand's economic and cultural dominance, most Lao people understand spoken Thai. Thai radio and television broadcasts, Thai pop songs, videos of Thai movies, and foreign movies dubbed in Thai are all popular in Laos; many educated Lao people also can read Thai. Thais, however, have more difficulty understanding Lao, partly through limited exposure to the language, and partly through a lack of desire to understand it, as they regard Lao as a language of low prestige.

Phonology and Grammar

Lao is a tonal language. Standard Lao has six tones: low, mid, high, rising, high falling, and low-falling. The vowel and consonant systems closely resemble those of standard Thai; notable difference are the existence of an

Thais, however, have more difficulty understanding Lao, partly through limited exposure to the language, and partly through a lack of desire to understand it, as they regard Lao as a language of low prestige.

Phonology and Grammar

Lao is a tonal language. Standard Lao has six tones: low, mid, high, rising, high falling, and low-falling. The vowel and consonant systems closely resemble those of standard Thai; notable difference are the existence of an

initial /ɲ/ and the absence of /r/ in spoken Lao. Grammatically, too, there are close similarities to Thai: word order is *subject-verb-object*, nouns and verbs are not inflected, the pronominal system is complex and capable of conveying subtle degrees of relative status and intimacy. 'Classifiers' or 'count words' are used in noun phrases involving numbers.

Words of purely Lao origin are often monosyllabic. Sanskrit and Pali borrowings are numerous, and where they coexist with an indigenous Lao word they reflect a more formal or literary style. Other sources of loan words are Thai, Chinese, and Cambodian, although with Thai and Lao sharing many common basic words, the extent of Lao borrowing can be overestimated; many relatively recently coined Thai words have, however, been consciously absorbed into Lao. Despite the country's former colonial status, French loan words are relatively few.

Recent History

When the boundaries of present-day Laos were drawn up in 1893 under the terms of a Franco-Siamese treaty, the Lao-speaking population was divided in two, the majority paradoxically being in northeast Thailand. The French brought in Vietnamese to carry out much of the administration of their colony, and with French the medium for what little postprimary education existed, the Lao language suffered a loss of prestige, even among many of its own speakers. The decline of French influence and the rise of nationalism in the aftermath of World War II helped to improve the status of Lao. Although the communist government, which came to power in 1975, has Lao-ized the education system, introduced adult literacy programmes and attempted to teach Lao to the country's ethnic minorities, literacy rates remain low.

The Lao People's Democratic Republic (Laos) is home to languages from at least four different 'genetic' groups: Tai (southwestern and northern branches), Mon-Khmer (Bahnaric, Katuic, Vietic, Khmuic, and Palaungic branches), Hmong-Mien (Hmongic and Mienic branches), and Tibeto-Burman (Lolo-Burmese branch). The precise number of languages spoken in the country is not known, due mainly to a lack of empirical data. Estimates vary between around 70 and around 120 distinct languages (Ethnologue 2004 lists 82). For a country of its size (smaller than the United Kingdom) and population (less than 5 million), Laos features a very high degree of linguistic diversity in global terms. This diversity is greatest in the country's hill and mountain areas, which account for some 70% of the land mass. Flatter stretches of land along rivers (especially along the Mekong River) are dominated by speakers of Lao.

Historical Background

Mon-Khmer languages appear to have been spoken in Laos longer than languages of other families. They show greater geographical spread and greater internal diversity. This is particularly apparent among languages of the Vietic, Katuic, and Bahnaric subgroups spoken throughout upland areas of the country's south. Many of these languages are near extinction, with very few remaining speakers (e.g., Thémarou, with only a couple of dozen speakers). Other languages, while small, are still being learned by children (e.g., Tariang (Talieng) with about 4000 speakers), although none show the vibrancy of the northern Mon-Khmer language Kmhmu (Khmu), with some 300 000 speakers throughout northern Laos. Tai languages such as Lao have their origins in southwest migrations of Tai speakers from southwestern China, beginning some 2000 years ago (Enfield, 2003: 47–50). Like their modern descendents, these incoming Tai speakers were in search of flat riverside land ideal for their trademark 'ditch-dike' system of wet-rice cultivation. The success of Tai languages and their speakers is attested to by their present dominance of the region, with Lao the official national language of Laos (Enfield, 1999), spoken as a first language by around half the population (more than two million people). (There are also approximately 20 million residents of northeast Thailand whose native dialects are closely related to Lao.) Hmong-Mien speakers are the newest arrivals in Laos, descended from migrants coming southwards from China within the last 200 years (Culas and Michaud, 2004).

Language Contact, Sociolinguistics, Multilingualism

Laos's high degree of linguistic diversity results in intensive language contact in most parts of the country. Upland peoples maintain structured social relations across ethnicities and language backgrounds, and are normally multilingual (Bradley, 2003). By contrast, lowland-dwelling people of Lao ethnicity tend to be monolingual. Some minority languages serve as contact languages within restricted upland areas. For example, Ngkriang (Ngeq) is used in interaction among several Katuic ethnic groups in isolated Kalum district, Sekong province.

Lao is the official language of administration, education, and major economic activity, and hence all minority communities have regular contact with Lao. Minority men are often more skilled than women and children in speaking Lao due to greater contact with the language, for example, during military service. Official promotion of Lao as a national language is served in part by the development of Lao language media and education, but this is slow thanks to the country's very weak infrastructure. Authorities widely encourage (and occasionally force) migration by minority peoples from upland areas to more accessible lowlands, ostensibly to ease the burden of social development in this poor nation. Internal migration is widespread, and in many cases this accelerates the process of attrition and loss of minority languages, due to division of already fragile speech communities and their resettlement together with speakers of other languages, in closer contact with the Lao-speaking world. The result is a widespread and rapid shift to Lao.

The two most prominent and vibrant minority languages of Laos are Hmong and Kmhmu, both spoken by large populations, mainly in northern Laos. Hmong speakers in particular show no signs of abandoning their language in favor of Lao. Hmong has a roman orthography that is taught unofficially and is in widespread use in Hmong society (e.g., in advertising, development, private correspondence, etc.). This contravenes the Lao government's official stipulation that no minority language is to be written in any orthography other than the Indic-based Lao script.

International languages with a significant presence in Laos include Thai and Vietnamese. Laos's longest borders are with Thailand to the west and Vietnam to the east. Lowland communities along the Mekong River are in intensive contact with Thai via electronic media, as well as through seasonal migration of Lao workers to Thailand. Thai and Lao are essentially dialects, making Thai especially accessible to Lao speakers. Vietnamese is less widely spoken as a second language (despite large urban communities of expatriate Vietnamese in the lowlands), but is used for economic purposes by many minority peoples living along the Vietnamese border. Through the colonial period of 1893 to 1954 (Evans, 2002), French was widely used in national education and administration. The use of French as an international language has since steadily diminished in favor of English.

Linguistic Research and Reference Materials

Comparatively little scientific research has been conducted on the languages of Laos. Descriptive studies of Lao include traditional European-style grammars (e.g., Hospitalier, 1937; Royal Lao Government, 1972; Reinhorn, 1980), dictionaries (Kerr, 1972; Reinhorn, 1970; Rehbein and Sayaseng, 2000), pedagogical materials (e.g., Yates and Sayasithsena, 1970;

Hoshino and Marcus, 1981), and work of a more technical linguistic nature (e.g., Roffe, 1946; Morev *et al.,* 1972; Crisfield, 1978; Wayland, 1996; Osatananda, 1997; Enfield, 2003, 2005). Available research on minority languages includes dictionaries (e.g., Lindell *et al.,* 1994; Preisig *et al.,* 1994 [Kmhmu]; Ferlus, 1999 [Nhaheun]), text collections (e.g., Costello and IRLCS, 1993 [Katu]), grammatical descriptions (e.g., Jacq, in press [Jruq]; Enfield, 2004 [Kri]), comparative word lists (e.g., Kingsada and Shintani, 1999; Wright, 2003), and historical-coparative work (e.g., Diffloth, 1982; Peiros, 1996; Sidwell, 2000; L-Thongkhum, 2002). Field research on languages of Laos is hampered not only by difficulties of transport and communications but also by severe restrictions imposed by the socialist government on research in the social sciences.

Lascaris, Jean (Laskaris, Janus) (ca. 1445–1534)

N Kerecuk, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Jean Lascaris was a distinguished Byzantine scholar who, along with other Byzantine scholars, greatly influenced mainly Western European but also Eastern European thought by reintroducing original Byzantine scholarship to the mainstream of academic activity after the fall of Constantinople in 1453. He is usually described as the younger brother of Constantine Lascaris.

Jean Lascaris first came to Venice under the patronage of the Cardinal Bessarion, who sent him to Padua to study Latin. He then took refuge in Florence under the patronage of Lorenzo de Medici. Lascaris developed a series of activities to promote Hellenistic scholarship. He lectured on ancient Greeks, such as the orator Demosthenes, the historian Thucydides, the dramatist Sophocles, as well as on literary works. Twice he traveled to Greece to acquire many original Greek manuscripts. Representing Lorenzo de Medici, he negotiated with Sultan Bayezid II for the acquisition of those manuscripts. In the 1490s, the press of Lorenzo Alopa began to work with and for Lascaris in Florence. Following the expulsions of Medicis from Florence in 1495, King Charles VIII of France invited Lascaris to Paris, where he taught Greek. He held various public offices and served as the ambassador in Venice (1503–1508). Then he became a member of the New Academy of Aldus Manutius. It has been suggested that Lascaris was a friend of and influenced Manutius, but there is no acknowledgement. In 1515, Lascaris accepted the invitation of Pope Leo X to direct the Greek Academy of Rome. Francis I of France employed Lascaris with Bude to move the Blois library to Fontainbleau, creating the Royal Library, which later was to become the National Library.

Lascaris either wrote or edited a number of works and, most importantly, a number of *editiones principes,* such as *Anthologia epigrammatum graecorum cura Joannis Lascaris* (1494), *Didymi Alexandrini scholia in Iliadem* (1517), *Homericarum quaestionum liber* (1518, Porphyrius of Tyre), and *De veris Graecarum literarum formis ac causis apud antiques* (1556). The introduction of Byzantine scholarship through original Greek language became relevant to the debates of the defense of the vernacular languages first in Italy, with Alessandro Citolini (*La Lettera d'Alessandro Citolini in difesa de la lingua volgare*, 1540) and Sperone Speroni (*Dialogo delle lingue,* 1542). The latter, in an imaginary debate in which P. Bembo confronts L. Bonamico on the use of Latin, includes another dialogue opposing P. Pomponazzi and Lascaris on the value of various languages and dialects (cf., Padley, 1988: 63–64).

The works of Constantine and Jean Lascaris as well the Byzantine works circulating in Western Europe affected Eastern European thought, particularly through the Orthodox Brotherhood Schools first in Ukraine and later among the East Slavs. The Lviv Dormition Brotherhood (established in 1463) became the model for other similar schools and disseminated humanist Greek traditions through its schools and presses. The Lviv Brotherhood published *Adelphotes*, the first Greek grammar, in 1591. Greek grammatical thinking left a mark on many of the subsequent grammars, both Greek and vernacular.

Lasch, Agathe (1879–1942)

J L Flood, University of London (Emeritus Professor), London, UK

© 2006 Elsevier Ltd. All rights reserved.

Prevented by her gender and her Jewish religion from becoming an academic librarian, Agathe Lasch, born in Berlin on July 4, 1879, instead qualified as a teacher in 1898 and worked in Berlin and Halle until 1906, when, at the age of 27, she passed her *Abitur*, which would permit her to study at a university. Although women were admitted to Prussian universities at that time, in practice this depended on each professor's discretion, and the distinguished Berlin medievalist Gustav Roethe would not countenance them in his lectures or seminars. With Berlin thus closed to her Lasch studied first under the Halle phonetician and dialectologist Otto Bremer and then at Heidelberg, where in 1909 she took her doctorate under Wilhelm Braune with a thesis on the supplanting of Low German (Plattdeutsch) by High German (German, Standard) in Berlin in the 16th century (Lasch, 1910). Glowingly reviewed by Edward Schröder (*Niederdeutsches Jahrbuch 26* (1910), 151–154), her study of the linguistic interaction of the chanceries of the Brandenburg rulers with other institutions and groupings of writers would serve as an authoritative model for the investigation of linguistic development in other towns.

From 1910 to 1916 she taught German at Bryn Mawr College in Pennsylvania. Although she enjoyed her work there, once the United States was about to enter the European war, she felt that as someone who admitted to being passionate about only two things, German philology and Germany (Hartau, 2002: 11), her place was at home. Thus, in 1916 she returned to Germany to work with Conrad Borchling on a dictionary of Hamburg German. When the University of Hamburg was formally established in 1919 she was appointed *Privatdozentin*, and in 1923 she became the first woman there to be awarded the title of Professor. From 1926 to 1934 she had special responsibility for Low German. After Hitler's accession to power in 1933, the National Socialists demanded the removal of Jews from office. Despite the intervention of colleagues in Sweden and Hamburg, Lasch was forced to retire in 1934. This development, though devastating, was not unexpected. She had saved some money, and in 1937 she moved to Berlin to live with her sisters. Jews were banned from public libraries; her own library was confiscated and her pension payments ceased. Her attempts to find employment abroad came to nothing: the German government prevented her from accepting invitations she received from Dorpat in 1939 and later from Oslo. On August 12, 1942 she was arrested, deported to the '*Reichsjudenghetto*' at Riga and was never seen again. The books she was preparing, including a study of the language of Lübeck city clerks and a history of Low German, never appeared.

Lasch's lasting memorial is her work on Middle Low German. Her *Mittelniederdeutsche Grammatik* (1914), prepared at Bryn Mawr, represented a considerable broadening of her earlier studies on Berlin, covering the Low German dialects from the 13th to the 17th centuries, the heyday of the Hanseatic League. Of her *Mittelniederdeutsches Handwörterbuch* she published the first fascicles, covering A–E, between 1928 and 1934. The *Hamburgisches Wörterbuch*, begun in 1917, started appearing under the editorship of J. Meier and D. Möhn in 1985 and is expected to reach completion sometime after 2010. Lasch was particularly interested in the language of Berlin: her 1910 dissertation was followed by *Berlinisch* (1928). Her focus was on the history of the Low German language in its cultural and political context. Thanks to her, Low German studies have come to be recognized as a distinct field of enquiry, and but for her pioneering work it is unlikely that Low German would have qualified for inclusion in the European Charter for Regional and Minority Languages (1998).

Her fate resulted in an outpouring of commemorative essays soon after the war (Borchling, 1946; Korlén, 1947; Jaatinen, 1947) and again on her centenary (Peters and Sodmann, 1979; Meier, 1980). For an assessment of her work in the broader context of Jewish scholarship, see Maas (1992) and Hass-Zumkehr (2001). In 1971 a street was named after her in Hamburg ('Agathe-Lasch-Weg'), and in 1991 a triennial Agathe Lasch Prize for promising scholars was established.

Lasswell, Harold Dwight (1902–1978)

M Garcarz, University of Warsaw, Warsaw, Poland

© 2006 Elsevier Ltd. All rights reserved.

Harold Dwight Lasswell (1902–1978), American sociologist, political philosopher, social psychologist, and psychoanalyst, was born on Friday the 13th, in Donnellson, Illinois. He was the son of a humble Presbyterian minister and a schoolteacher. From the very beginning, Lasswell was intensely engaged in the social matters of his times. During his school years he was an editor of the school newspaper and a pupil actively involved in school life. When he was 16, he received a scholarship to attend the prestigious University of Chicago. He graduated from there in 1922, and, in 1926, he received his Ph.D. Lasswell then attended the London School of Economics and also studied in Geneva, Paris, and Berlin, where he first had the opportunity to study psychoanalysis for sociopolitical purposes. For the next eight years he taught at the University of Chicago as a professor of social sciences. He was also a professor at Milikan University and at Columbia University, but soon after that, in 1938, Lasswell left Chicago to teach at Yale University. In 1946 he became a professor of law and political sciences and, in 1952, became a full professor of political sciences at Yale. During WW II Lasswell was a director of War Communication Research at the Library of Congress in Washington. He also taught at the John Jay College of the City of New York and was a consultant for various departments of the federal government. During 1955–1956, he was the president of the American Association of Political Sciences. In 1963 Lasswell retired from Yale University.

On the one hand, Lasswell, as a political philosopher and theoretician, was highly interested in the mechanisms that rule the contemporary political scene. On the other hand, as a social psychologist Lasswell desired to investigate the ethics and the sociocultural factors that profoundly influence those mechanisms.

Lasswell's activity as a political theoretician brought about a formulation of an assumption that politics in general is a broader concept than just a simple field of human to human relationships. He wanted to prove that the notion of politics had a more complex nature that should be investigated from the psychoanalytic angle. He created the methodological basis for the study of contemporary politics which covers the activity of humankind on many levels. At the end of the 1920s and into the early 1930s, Lasswell became an orthodox follower of Freud's ideas concerning psychoanalytical psychology, and he applied those ideas to his political science research. Later, when the concept of psychoanalysis

Harold Dwight Lasswell (1902–1978), American sociologist, political philosopher, social psychologist, and psychoanalyst, was born on Friday the 13th, in Donnellson, Illinois. He was the son of a humble Presbyterian minister and a schoolteacher. From the very beginning, Lasswell was intensely engaged in the social matters of his times. During his school years he was an editor of the school newspaper and a pupil actively involved in school life. When he was 16, he received a scholarship to attend the prestigious University of Chicago. He graduated from there in 1922, and, in 1926, he received his Ph.D. Lasswell then attended the London School of Economics and also studied in Geneva, Paris, and Berlin, where he first had the opportunity to study psychoanalysis for sociopolitical purposes. For the next eight years he taught at the University of Chicago as a professor of social sciences. He was also a professor at Milikan University and at Columbia University, but soon after that, in 1938, Lasswell left Chicago to teach at Yale University. In 1946 he became a professor of law and political sciences and, in 1952, became a full professor of political sciences at Yale. During WW II Lasswell was a director of War Communication Research at the Library of Congress in Washington. He also taught at the John Jay College of the City of New York and was a consultant for various departments of the federal government. During 1955–1956, he was the president of the American Association of Political Sciences. In 1963 Lasswell retired from Yale University.

On the one hand, Lasswell, as a political philosopher and theoretician, was highly interested in the mechanisms that rule the contemporary political scene. On the other hand, as a social psychologist Lasswell desired to investigate the ethics and the sociocultural factors that profoundly influence those mechanisms.

Lasswell's activity as a political theoretician brought about a formulation of an assumption that politics in general is a broader concept than just a simple field of human to human relationships. He wanted to prove that the notion of politics had a more complex nature that should be investigated from the psychoanalytic angle. He created the methodological basis for the study of contemporary politics which covers the activity of humankind on many levels. At the end of the 1920s and into the early 1930s, Lasswell became an orthodox follower of Freud's ideas concerning psychoanalytical psychology, and he applied those ideas to his political science research. Later, when the concept of psychoanalysis

was no longer fully efficient as far as its application to political research was concerned, Lasswell turned to investigating the theoretical basis of democracy and the means that should be taken to uphold it.

Lasswell's academic and scientific works can be separated into two distinct periods, early and late. In the first period, during the 1930s and 1940s, Lasswell was convinced that innate logic is fully functional only when accompanied by ethic values which an individual acquires during his or her upbringing. He also claimed that according to the Freudian concept of natural instincts (e.g., Oedipal's complex), personal motives for the sociopolitical activity of politicians are shaped by their moral values, learned in childhood. In one of his first books, *Psychopathology and politics*, he explains the complexity of the socioethic processes which shape the mental stability of a fully conscious *homo politicus*. Such an individual is a unique combination of motivations and certain interpersonal skills, which, to a very great extent, influences his or her political orientation. In his research, Lasswell pays particular attention to the concept of political propaganda and the credibility of politicians as actors on the political scene. In his famous 'Models of communication,' Lasswell explains how that message, as a basic ingredient of propaganda, goes:

> *Who (says) What (to) Whom (in) What Channel (with) What Effect*

'**Who**' is the side controlling the message transfer in the media, '**says what**' is the true subject matter of the transmitted message, '**to whom**' is the receiver of the final message, '**in what channel**' stands for the means applied to transmit the message, and '**with what effect**' is the impression that the entire message transmission makes on the text receiver. For Lasswell, propaganda is a technique of modeling people's activity and shaping the attitudes of social groups toward particular political issues. Lasswell views politics as a ruthless and hermetic system of a mutual dependency of individuals who should remain loyal to the system itself. The manipulation of symbols for political purposes is, according to Lasswell, immoral from the general assumption. In the 1930s and early 1940s, Lasswell's studies of the issue of personality and politics contributed greatly to behavioral science. However, in his works from the late 1940s, there was a gradual change in Lasswell's interests.

In the second period of his scientific and public activity (the early 1950s), Lasswell was a political scientist who laid the foundation of the American theoretical cultural neopsychoanalytical theory. In *World revolutionary elites studies in coerci* (published in 1965), Lasswell elaborates his definition of elites. He claims that there are three distinct basic needs of contemporary society, which political elites must satisfy in order to uphold their real political power: prestige, income(s), and the feeling of security for fellow citizens. According to a neo-Freudian concept of the ego-psychology (the self-sense system of a person), only political scientists possess the precise instruments to monitor the political tensions within an investigated social or ethnic group, to help the elites in sustaining the political system. The experts in political sciences should take responsibility for making the political system comprehensible and transparent to voters, and universal for the ruling elites. Lasswell's approach toward politics radically changed at the end of the 1950s and into the 1960s, when he started to promote the concept of politics directed at an individual. For Lasswell, a mentally and morally sane man is the basic element of a sane community. He claimed that contemporary societies needed, e.g., 'political psychiatrists' who would prevent war and global conflicts. According to Lasswell, political stability from a global perspective resulted from the bipolar system of balancing power between the USSR and the United States.

Lasswell was also deeply interested in the concept of democratic systems. In short, he explained that democracy is the effect of global stability. On the one hand, Lasswell was of the opinion that democracy is a political system that did not satisfy the needs of individuals, but rather the community as a whole. On the other hand, he thought that political crusades that were aimed at changing the general structure of a political system brought no results unless the individuals gained economic stability. Lasswell believed that in times when traditional ethic values were diminishing, and the threat of nuclear conflict was becoming more and more real, people gradually changed their attitude toward moral issues which were the permanent cornerstones of democracy.

In his research, Laswell applied only theoretical psychoanalysis. He never practiced as a clinical specialist; therefore, his research could be treated as an incomplete or a unilateral description of human personality functioning in real politics. It is vital to highlight that Lasswell does not criticize the idea of politics, or political ideas, but the manner in which politics is served to the average voter, citizen, and human.

Latacz, Joachim (b. 1934)

V Van Elst, Seminarium Historiographiae Linguisticae, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Joachim Latacz is Professor Emeritus of Greek Philology at Basel University. Having specialized in early Greek epic and lyric, Greek tragedy, Alexandrian poetry, and the history of Troy, he has especially developed into a distinguished Homeric scholar. His aim to bring Homer nearer to a broad but discerning public has led to a series of captivating lectures and much-quoted articles in this field, as well as to several creditable, widely known books.

Born in Kattowitz, Latacz studied classics, ancient history, philosophy, Slavonic (Slavonic, Old Church), and comparative Indo-European linguistics at the universities of Halle (Saale), Berlin, and Hamburg (1953–1960). While collaborating on the *Lexikon des frühgriechischen Epos* (*LfgrE*) in Hamburg under the direction of B. Snell and H. Erbse (1960–1965), he obtained his doctoral degree at the Free University Berlin in 1963 with a dissertation on the semantic field 'joy' in the Homeric language (1966). After qualifying to teach at the university in Würzburg in 1972, he was appointed full professor in Mainz in 1978. Since 1981, his scholarly activities have taken place in Basel, where he was accorded emeritus status in 2002.

Among Latacz's most famous publications are his books *Homer* (1st edn. 1985) and *Troia und Homer* (1st edn. 2001), both reedited several times and translated into other languages. While the former puts the poetical and aesthetical qualities of the Homeric epopees in the forefront, the latter highlights the historical reality behind the Trojan War epic, invigorated by recent archaeological discoveries and fresh impulses from many other disciplines related to ancient history. Latacz's expertise indeed covers a whole range of research areas, varying from oriental studies to cognitive psychology. Specifically for linguistics one can mention his constant interest in the Homeric language (cf., e.g., *LfgrE* and 1966), including its formulaic, oral, and improvisatory features. In search of the historical core of the Trojan legend, he has mastered Hittite and Mycenaean too (cf., e.g., 2002).

In April 2004 Latacz celebrated his seventieth birthday. Still, his life's work of keeping Homer alive is not finished. He is currently working on his most ambitious project ever, launched in 1995: the composition of a German commentary on the *Iliad*. Because its predecessor (the edition of K. F. Ameis and C. Hentze) dates from 1868–1913 and because Homeric scholarship has since been enriched with many new insights and perspectives (including the oral-poetry theory introduced by M. Parry in 1928), Latacz's commentary will undoubtedly be a great addition to the German tradition of 'Homer-Forschung.' The commentaries on the first two books have already been published, and those on books 3, 6, 9, 19, 22, and 24 are expected in the coming years.

Latent Semantic Analysis

P Wiemer-Hastings, DePaul University, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Latent semantic analysis (LSA) is a technique for creating vector-based representations of texts that are claimed to capture their semantic content. The primary function of LSA is to compute the similarity of text pairs by comparing their vector representations. This relatively simple similarity metric has been situated within a psychological theory of text meaning and has been shown to closely match human capabilities on a variety of tasks.

This article follows the developmental path of LSA, describing its historical context, showing how it computes and uses its vector representations, and then giving examples of the theoretical and empirical support for LSA and its current research directions.

How LSA Works

LSA (originally known as latent semantic indexing) was developed for the task of information retrieval, that is, selecting from a large database of documents a few relevant documents that match a given query. Previous approaches to this task included keyword matching, weighted keyword matching, and vector-based representations based on the occurrence of words in documents. LSA extends the vector-based approach by using singular value decomposition (SVD) to reconfigure the data. The details of this process are described following, but the intuition is that there is a set of underlying latent variables that spans the meanings that can be expressed in a particular language. These variables are assumed to be independent (and therefore orthogonal in the vector space). SVD is a matrix algebra technique that essentially reorients and ranks the dimensions in a vector space.

Because the dimensions in a vector space computed by SVD are ordered from most to least significant, if some of the less-significant dimensions are ignored, the reduced representation is guaranteed to be the best possible for that dimensionality. In LSA, the typical assumption is that only the top 300 or so dimensions (out of tens or even hundreds of thousands) are useful for capturing the meaning of texts. By basing the representations on a reduced number of dimensions, words that generally occur in similar contexts have similar vectors and will, therefore, get a high similarity rating. The discarded dimensions are assumed to be the product of noise, random associations, or some other nonessential factor.

That LSA performed information retrieval better than its rival approaches is not especially surprising. What is more surprising is how well it models human behavior on a variety of linguistic tasks. Before describing these, however, the LSA technique is described in more detail.

Although there are some variations, the most common steps are these:

- Collect a large set of (domain-relevant) text and separate it into 'documents.' For most applications, each paragraph is treated as a separate document based on the intuition that the information within a paragraph tends to be coherent and related.
- Next, create a co-occurrence matrix of documents and terms. The cell in this matrix corresponding to document x and term y contains the number of times y occurs in x. A term is defined as a word that occurs in more than one document, and no stemming or other morphological analysis is performed to try to combine different forms of the same word.

If there are m terms and n documents, this matrix can be viewed as giving a representation that has an m-dimensional vector for each document, and an n-dimensional vector for each term.

- The values in each cell may be weighted to reduce the effect of common words that occur through the corpus. A common weighting method is 'log entropy,' based on information theory, which multiplies the value by its information gain.
- SVD is invoked with a parameter k, which specifies the desired number of dimensions. (In principle, the SVD would be computed with all the dimensions to create three matrices that, when multiplied together, would produce the original data, but due to the amount of memory that this would require, this is not feasible. Instead, the currently used algorithms are optimized for dealing with sparse data spaces and compute only the most significant k dimensions of the matrices.)

The result of the preceding processing is three matrices. One has a k-dimensional vector for each document, one has a k-dimensional vector for each term in the corpus, and one has the k singular values. The first two matrices define two different vector spaces that are also different from the space defined by the original matrix. The singular values can be used to transform a vector from one space to the other. The use of these matrices depends on the application.

For information retrieval, the document vectors contain the LSA representation of each document. A query is turned into a 'pseudodoc' in the document vector space by combining the vectors for the terms in the query and dividing by the singular values. Vectors are typically compared by computing the cosine between them. (Some applications use other distance metrics.) The closest vectors from the document vector space correspond to the documents that are closest in meaning to the query (according to LSA).

In most other applications, the original documents are only used for training, that is, creating the semantic space. To compare new texts, the term vectors are combined as described earlier. Here, no manipulation with the singular values is required because the vectors are compared in the term space.

For more details about the mathematical foundations of LSA, see Golub and Van Loan (1989) and Hu *et al.* (2005). For more details about the creation of LSA spaces, see Deerwester *et al.* (1990) and Quesada (2005a).

Support for LSA

Support for LSA might be said to stem from the time of World War II when Wittgenstein wrote (what was later translated as):

> . . . for a large class of cases – though not for all – in which we employ the word "meaning" it can be defined as thus, the meaning of the word is its use in language. (Wittgenstein, 1958: 20)

A large number of psychological studies have taken Wittgenstein's words to heart and shown that LSA's behavior is closely matched with that of humans, for example:

- LSA acquires words at a similar pace to human children, sometimes exceeding the number of words to which it is exposed (see Landauer and Dumais, 1997).
- LSA's knowledge of synonyms is as good as that of second-language English speakers as evidenced by scores on the Test of English as a Foreign Language (TOEFL, see Landauer *et al.*, 1997).
- LSA can tell students what they should read next to help them learn (see Rehder *et al.*, 1998).
- LSA can even interpret metaphors such as, "My lawyer is a shark" (see Kintsch, 2001).

For textual applications, LSA has another benefit besides its high correlation with human behavior. When compared with the traditional labor-intensive approach to natural language processing – developing a grammar, a lexicon, a semantic representation, and the processing engine needed to combine them – developing an LSA-based representation is quite simple. It also has the advantage of graceful degradation. If it doesn't know a word, LSA simply ignores it and bases its representation on the other words. This has led researchers to use LSA for a variety of applications, including

- Intelligent tutoring systems that allow students to enter unconstrained natural language replies to questions (see Graesser *et al.*, 2000 and Wiemer-Hastings *et al.*, 2004)
- Grading psychology essays by comparing them to pregraded essays (see Foltz, 1996)
- Evaluating summaries of documents to help teach summarization skills (Summary Street, described at http://colit.org/)
- Helping students learn to properly integrate and cite material from multiple documents (see Britt, 2005)
- Evaluating airplane landings in a flight simulator (see Quesada, 2005b).

The only applicability constraints for LSA are that the task is text based, it can be framed in terms of computing the similarity of texts, and there is an available training corpus. The tutoring systems, for example, compare a student's answer for a question to a set of expected answers. If the student's response is close enough to a good answer, then the system gives positive feedback and moves on to the next question. If the student's answer matches an expected bad answer, then the system steers the student back on track.

Issues

The research issues facing the LSA community range from the practical to the philosophical. One basic question addresses the size and substance of the training corpus. Many effective LSA applications have been developed using relatively small corpora. In one of the successful applications mentioned earlier, LSA was trained on a corpus of only a couple hundred kilobytes with 2000 word types, 30 000 word tokens, and 325 documents. In contrast, researchers at the University of Colorado have reported that they have trained LSA on a corpus containing 750 000 word types, 550 million word tokens, and 3.6 million documents.

Unfortunately, there is little hard evidence on what the ideal size of an LSA corpus might be. The current data suggests that adding extra texts is unlikely to reduce performance, so a basic rule of thumb is, the more the better.

The obvious follow-up question is, 'What kinds of text should be included in an LSA corpus?' The

common wisdom holds that the corpus should consist of texts that are relevant to the particular target task. The domain can define a sublanguage where words are interpreted in consistent ways. Furthermore, a primary concern is to achieve sufficient coverage of the words that will be encountered in the course of running the application. A domain-specific corpus will have a higher percentage of relevant words and will thus not waste its representational power on words that will not be seen by the application.

One critical objection that is raised against the LSA approach is that not only does it ignore the syntactic structure of sentences, it also even ignores word order. In other words, LSA treats a text as a bag of words. In practice, LSA does well with longer passages of words (defined by Rehder, 1998, as more than 200 words), where syntactic details may be 'washed out,' and it also does well with single words (the TOEFL test, for example), but it does not do well on single sentences as shown by Wiemer-Hastings *et al.* (1999). A variety of approaches have attempted to deal with this, including surface parsing of sentences so that the components can be compared separately with LSA and using string edit theory to infer structural relations (see Wiemer-Hastings and Zipitria, 2001; Kanejiya *et al.*, 2003; Dennis, 2005).

Another notable gap in LSA's competence is negations, either because they are omitted from the LSA training via a stop words list or simply because their widespread use throughout a corpus renders them representationally depleted. Although no satisfactory approach yet exists for dealing with negations, a possibility would be to treat them as an essentially syntactic component that can processed as described earlier.

A more fundamental question about LSA is what its dimensions mean. Because they represent latent variables, there is no clear definition. As shown by Hu *et al.* (2003), there is a high correlation between the first dimension and the frequency of occurrence of the words in the corpus. Beyond that, there are no clear answers. There is also considerable debate as to what extent LSA captures first-order co-occurrence or higher-order co-occurrence. Recent evidence from Denhière *et al.* (2005) shows that although second-order effects do occur, large changes in the similarity measure between two words can be seen when a document is added to a training corpus in which both words occur (first-order co-occurrence).

LSA's utility and correspondence with human behavior have made it a popular technique for psycholinguistic research and text processing. The issues described here (along with others, for example, 'Is LSA at all psychologically plausible?') will keep researchers busy for years to come. A collection edited by McNamara *et al.* (2005) provides considerably more detail about the current practice and research on LSA.

Laterality Across the World's Languages

J B Hellige and M M Adamson, University of Southern California, Los Angeles, California, USA

© 2006 Elsevier Ltd. All rights reserved.

The left cerebral hemisphere is superior to the right for many aspects of speech processing and reading. This overall left-hemisphere dominance is ubiquitous across the world's languages. However, as laterality research has expanded to include a wider variety of languages, we have learned that subtle characteristics of hemispheric asymmetry that were once treated as universal may, instead, depend on specific characteristics of a language. This seems to be particularly true for what has been termed the qualitative nature of processing printed material. With this in mind, this review highlights both the overall consistency and the variability in laterality across the world's languages. Although the review is, of necessity, illustrative rather than exhaustive, it will serve to demonstrate the importance of cross-linguistic laterality studies and to suggest factors that contribute to variability. After a brief review of laterality for identifying speech sounds, we provide a somewhat more extensive review of laterality for identifying printed words and nonwords. In each case, studies using English are reviewed first to provide a context in which to understand studies with other languages.

Processing Speech Sounds

There is a good deal of converging evidence of left-hemisphere superiority for most aspects of speech processing. Though most of the evidence comes from studies of English, laterality for speech processing has been examined across a sufficient variety of languages to demonstrate the generality of left-hemisphere superiority and to suggest a few critical factors that underlie such laterality.

English

Studies of patients with unilateral brain damage, behavioral laterality studies, functional brain imaging studies, and studies using a variety of other techniques all indicate left-hemisphere superiority for identifying acoustically presented words and nonwords. For example, in a behavioral technique known as dichotic listening, two similar but different sounds (e.g., */ba/* and */da/* or */bad/* and */dad/*) are presented simultaneously, one to each ear. Because input pathways from each ear project predominantly to the contralateral cerebral cortex, better identification of the stimuli from one ear is taken to reflect superior processing in the contralateral cerebral hemisphere. For English speakers processing English speech sounds, there are remarkably consistent indications of a right-ear (that is, left-hemisphere) advantage for most people.

Laterality Across the World's Languages

J B Hellige and M M Adamson, University of Southern California, Los Angeles, California, USA

© 2006 Elsevier Ltd. All rights reserved.

The left cerebral hemisphere is superior to the right for many aspects of speech processing and reading. This overall left-hemisphere dominance is ubiquitous across the world's languages. However, as laterality research has expanded to include a wider variety of languages, we have learned that subtle characteristics of hemispheric asymmetry that were once treated as universal may, instead, depend on specific characteristics of a language. This seems to be particularly true for what has been termed the qualitative nature of processing printed material. With this in mind, this review highlights both the overall consistency and the variability in laterality across the world's languages. Although the review is, of necessity, illustrative rather than exhaustive, it will serve to demonstrate the importance of cross-linguistic laterality studies and to suggest factors that contribute to variability. After a brief review of laterality for identifying speech sounds, we provide a somewhat more extensive review of laterality for identifying printed words and nonwords. In each case, studies using English are reviewed first to provide a context in which to understand studies with other languages.

Processing Speech Sounds

There is a good deal of converging evidence of left-hemisphere superiority for most aspects of speech processing. Though most of the evidence comes from studies of English, laterality for speech processing has been examined across a sufficient variety of languages to demonstrate the generality of left-hemisphere superiority and to suggest a few critical factors that underlie such laterality.

English

Studies of patients with unilateral brain damage, behavioral laterality studies, functional brain imaging studies, and studies using a variety of other techniques all indicate left-hemisphere superiority for identifying acoustically presented words and nonwords. For example, in a behavioral technique known as dichotic listening, two similar but different sounds (e.g., */ba/* and */da/* or */bad/* and */dad/*) are presented simultaneously, one to each ear. Because input pathways from each ear project predominantly to the contralateral cerebral cortex, better identification of the stimuli from one ear is taken to reflect superior processing in the contralateral cerebral hemisphere. For English speakers processing English speech sounds, there are remarkably consistent indications of a right-ear (that is, left-hemisphere) advantage for most people.

Right-ear advantages have been reported for nonwords as well as for words and for a variety of speech sounds including stop consonants, nasals, and vowels (for review, see Hellige, 1993). Recent neuroimaging studies indicate bilateral activation in the region of the superior temporal gyrus, though the amount of activation appears asymmetric. Activation of additional regions depends on the specific task being performed (for review, see Hickok and Poeppel, 2004).

Though there is consistent evidence for a left-hemisphere advantage in identifying which speech sounds have been presented, there are strong indications of a right-hemisphere advantage for identifying such things as the emotional tone conveyed by a word or short sequence of words or for other forms of speech prosody. In fact, within the same dichotic listening study, simultaneous right-ear (left-hemisphere) and left-ear (right-hemisphere) advantages have been shown for identifying word content and emotional tone, respectively (Bryden and MacRae, 1989; Grimshaw *et al.*, 2003).

An important area for additional investigation concerns the extent to which effects like those just noted are related to language or to the perception of emotion, per se, or whether they are related to more general hemispheric asymmetry for processing different aspects of acoustic signals. For example, information about the identification of many spoken phonemes in English is conveyed by rapid changes in the acoustic signal over brief periods of time, a type of acoustic change for which the left hemisphere is hypothesized to be well-adapted, whether the stimuli are linguistic or not. In contrast, information about emotional tone of voice is conveyed by much slower modulations of the acoustic signal over longer periods of time, a type of acoustic change for which the right hemisphere is hypothesized to be well adapted (e.g., Bryden and MacRae, 1989; Grimshaw *et al.*, 2003; Hellige, 1993).

Other Languages

Laterality studies using a variety of the same techniques that have been used with English demonstrate similar effects across other languages. This includes a variety of European languages as well as languages that, unlike English, use pitch for lexical purposes (e.g., Mandarin Chinese, Thai, and Vietnamese). It is interesting that, in those languages for which phonemic and lexical discriminations are made on the basis of pitch, the left-hemisphere advantage extends to pitch discriminations presented in the context of linguistic discrimination. This stands in contrast to studies of native English speakers in which there is no consistent left-hemisphere dominance (and even some indication of right-hemisphere dominance) for pitch discrimination. Such results do not necessarily argue against the notion that some of the hemispheric asymmetry for speech perception is related to a more general hemispheric asymmetry for processing different types of acoustic information. However, they indicate that, in addition to this, laterality for a specific acoustic property also depends on that property's relevance for making linguistic discrimination in the language being tested.

Processing Printed Words and Nonwords

The left hemisphere is superior to the right for most aspects of processing written or printed words and nonwords. As is the case for speech processing, there are several types of converging evidence, including studies of patients with unilateral brain damage, behavioral laterality studies, and studies of localized brain activity. The greatest amount of evidence again comes from studies of English, though there are now at least some studies in a great many other languages. Though left-hemisphere superiority for certain aspects of processing is widespread, there are interesting exceptions related to specific characteristics of individual languages. As illustrated by the following brief review, variability across languages is especially noteworthy with respect to what have been termed qualitative aspects of processing.

English

A brief review of laterality studies using English provides a context in which to consider laterality across other languages. A great many studies of patients with unilateral brain damage indicate that processing printed words and nonwords is more likely and more severe when the left hemisphere is damaged than when it is not. Furthermore, neuroimaging studies of brain-damaged patients as well as neurologically normal individuals provide evidence of greater left-hemisphere activation during processing of printed words and nonwords in English (e.g., Pugh *et al.*, 1997, 2001; Cohen *et al.*, 2000; Polk *et al.*, 2002; Mechelli *et al.*, 2003; Price *et al.*, 2003). However, specific cerebral activation patterns differ for various components of reading and may include semantic, phonological, and orthographic networks (Pugh *et al.*, 1997, 2001). For instance, silent reading of words, nonwords, letter strings, and psuedowords in English leads to greater activation in left hemisphere, as compared to in the right hemisphere, mainly in the left inferior frontal gyrus, left anterior insula, frontal operculum, left temporoparietal junction, left inferior occipital gryus, and posterior portion of left inferior

temporal area (e.g., Rumsey *et al.*, 1997; Cohen *et al.*, 2000; McCandliss *et al.*, 2003). In addition, nouns and object names in English activate the posterior regions of occipitotemporal and occipital areas, whereas verbs and action names activate the prefrontal and frontal temporal regions (Pulvermuller *et al.*, 1999). Furthermore, the pattern and strength of activation in these areas may depend on the particular properties of different languages that share the same alphabet system. For example, reading of words and nonwords in Italian, an orthographically shallow language compared to English, leads to greater activation in the left superior temporal region as compared to the homologous region in the right hemisphere, whereas reading in English shows greater activation in left frontal and posterior inferior temporal regions (Paulesu *et al.*, 2000).

Converging evidence of functional left-hemisphere superiority also comes from a variety of behavioral studies, including studies that flash visual material very briefly to the left or right of an observer's point of eye fixation. This technique is based on the fact that each visual half-field projects directly to the contralateral brain hemisphere, so that under appropriate conditions, an advantage for one visual field or the other is a reflection of an advantage for one hemisphere or the other. A great many studies in English demonstrate a right visual field (RVF) or left-hemisphere advantage for such things as identifying printed words and nonwords (for review, see Hellige, 1993) or for indicating whether or not a string of printed letters spells a word (a lexical decision task; for examples, see Iacobani and Zaidel, 1996).

In addition to demonstrations of left-hemisphere superiority, there is evidence that printed material may be processed in qualitatively different ways by the left and right brain hemispheres. For example, it has been suggested that the right hemisphere tends to process the letters within a word or even within a pronounceable nonword in a relatively slow, sequential manner, whereas the left hemisphere tends to process the letters within the string in a more holistic or parallel manner. For example, some patients with left-hemisphere injury, whose reading is thought to depend more on the intact right hemisphere, read words laboriously, in a letter-by-letter manner (e.g., Reuter-Lorenz and Baynes, 1992). In addition, in a variety of visual half-field experiments that require word naming or lexical decision, there are word-length effects when stimuli are projected to the left visual field (LVF) or right hemisphere but not when stimuli are projected to the RVF or left hemisphere. That is, in LVF/right hemisphere trials, reaction time and errors increase as word length increases, consistent with the suggestion of slower, serial processing. Interestingly, when words are presented in unusual formats (e.g., the letters are arranged vertically, the letters are misaligned or of mixed case), word-length effects of the same magnitude have been reported for both LVF/right hemisphere and RVF/left hemisphere trials (Young and Ellis, 1985; Lindell *et al.*, 2002). Thus, the ability of the left hemisphere to process printed words in a more parallel manner may be restricted to stimulus arrangements that are typical of English.

Converging evidence for qualitative differences on LVF and RVF trials also comes from studies that required observers to identify consonant-vowel-consonant (CVC) nonword letter sequences (e.g., 'dag'). Across many such studies, there is a robust RVF/left hemisphere advantage for this task. In addition, distinctively different error patterns are obtained on LVF and RVF trials. On LVF trials, the third letter is missed more often than the first letter, just as one would expect if the letters were being processed in a relatively slow, sequential manner. On RVF trials, this difference between first and third letter errors is reduced and may even be eliminated if the letters are arranged in the typical horizontal manner. It has been suggested that this reflects the special ability of the left hemisphere to treat the CVC stimulus as a single pronounceable unit rather than as a simple collection of individual letters (for examples and review, see Hellige and Marks, 2001; Marks and Hellige, 1999, 2003). Thus, examination of these qualitative error patterns may shed light on the manner in which processing depends on characteristics that differ across the world's languages. In fact, as the subsequent review demonstrates, qualitative aspects of processing seem to be quite a bit more variable than the more prevalent quantitative advantage for the left hemisphere.

Much research with European languages produces laterality patterns very similar to the patterns reported for English and, consequently, will not be reviewed here. Instead, we focus on selected languages whose laterality patterns differ in interesting ways from those found with English. To help set a context for understanding the laterality effects, each of the following language-specific sections begins with a brief overview of the characteristics of printed text in that language and is followed by a summary of what is known about laterality for processing that text. Following these sections, we suggest some general factors that may be related to variability across languages in both quantitative and qualitative aspects of laterality.

The proto-Semitic system that gave rise to Hebrew, Arabic, Farsi, Urdu, and Sanskrit consisted mainly of consonants; the markings of vowels and their pronunciations was made optional. These scripts continue to

have several common features, including the fact that the modern versions of each typically omit vowel markings and the fact that all except Sanskrit are scanned from right to left. Of course, each of these languages also has its own unique morphology as well as other characteristics that may influence laterality. With these things in mind, the next several sections review laterality for Hebrew, Arabic, Farsi, and Urdu.

Hebrew

Written Hebrew words are produced when semantic roots are embedded with vocalic indications and syllabic prefixes or suffixes. Written Hebrew consists of a string of consonants, in the sense that there are no separate characters to designate vowels. Instead, four of the consonantal letters are also used to designate vowels, creating a good deal of ambiguity. A 'pointed' form of text uses diacritical marks to identify correct vowel pronunciation and location. This form has perfect grapheme-to-phoneme correspondence so that words can be easily pronounced. The typical modern form of Hebrew text is 'unpointed,' omitting the diacritical marks, producing a deep orthography and many homographs (words that are spelled the same but pronounced differently). This is generally thought to lead to a lexical reading strategy, in which an entire word is processed before phonological information is extracted postlexically (Bentin *et al.*, 1984; Share, 2003). Just as in English, processing of printed Hebrew text is disrupted more by left-hemisphere damage than by right-hemisphere damage. At the same time, more subtle differences in dyslexic symptoms are almost certainly related to specific characteristics of Hebrew. For example, studies of surface dyslexia in Hebrew speakers show that the patients are able to read nonwords and other phonological transformations when the material is presented in pointed form but are unable to read unpointed Hebrew (Birnboim, 1995). Whereas in English surface dyslexics have difficulty with irregular (exception) words (Marshall and Newcombe, 1973; Patterson, 1981; Coltheart *et al.*, 1983) most of the errors made in Hebrew are attributable to misreading of the vowels, leading to a very selective type of peripheral dyslexia. The specific function impaired in these patients is the ability to locate the position of a vowel within a word while letter identification itself is intact (Friedman and Gvion, 2001).

In behavioral studies of Hebrew, there is a robust RVF/left hemisphere advantage for naming printed words and nonwords as well as for making lexical decisions (Faust *et al.*, 1993; Babkoff *et al.*, 1997; Lavidor *et al.*, 2002). Thus, quantitative aspects of laterality are very similar to those found with English. However, qualitative aspects of laterality are sometimes quite different. For example, experiments investigating word-length effects in Hebrew have produced mixed results. Similar to English, some studies show word length has an effect only on LVF/right hemisphere trials in Hebrew during lateralized lexical decision tasks (Lavidor *et al.*, 2002). However, other studies, using similar methodology, show length effects in both visual fields (Koriat, 1985; Lavidor *et al.*, 2001), and studies of other types indicate the opposite result from English (Nazir *et al.*, 2004). In addition, in studies that required identification of CVC nonword stimuli, the visual field difference in qualitative error pattern was opposite that reported for similar studies English, at least when the letters were presented vertically. That is, there were more third-letter errors than first-letter errors on RVF/left hemisphere trials, and this difference was reduced on LVF/right hemisphere trials (Eviatar, 1999). It is important to keep in mind the fact that even though this qualitative aspect of laterality was reversed for the two languages, there were equally robust RVF/left hemisphere accuracy advantages in both. In considering the qualitative differences between Hebrew and English, Eviatar (1999) suggests that relevant factors may include the difference in scanning direction as well as the possibility that the morphology of unvoweled (unpointed) Hebrew (which was used in her study) is such that the entire stimulus may have to be scanned because letters of the root are dispersed across entire words. From this perspective it is interesting that there was no visual field difference in qualitative error patterns when the Hebrew nonwords were presented with the letters arranged in the more typical horizontal manner.

Arabic

In Arabic, Farsi and Urdu letters are connected in script-like fashion to form words or pronounceable nonwords. This means that each letter may be represented by two to four distinct allographs, depending on its position in word-initial, word-medial, word-final, or isolation. For Arabic, 22 of 28 letters in the alphabet have four shapes each (word initial, medial, final, and when they come after an unconnecting letter). Six other letters have two shapes each (Ibrahim *et al.*, 2002). Arabic has two forms: literary Arabic, which is taught in schools as the standard script for reading and writing, and modern Arabic, which is the native language of Arabs. Although the two forms of Arabic share orthographic properties, they are phonologically and syntactically different. More specifically, certain vowels exist in modern Arabic but are considered illegal in literary Arabic. Other

differences include usage of different word order constraints in sentence structure, employing different plural markings and insertion rules for function words (Bentin and Ibrahim, 1996). Arabic orthography, similar to Hebrew, has two forms, one in which the vowels are marked, and another in which they are not marked. As in Hebrew, if all the vowels are marked, above or below the letters in a word, literary Arabic is phonologically transparent. If the vowel marks are not included, the orthography becomes opaque (Bentin and Ibrahim, 1996). However, unlike Hebrew, the four letters that designate long vowels in Arabic do not also function as consonants, and inclusion of them in a word helps the pronunciation. Modern Arabic does not include the vowel markings, but the letters designating the vowels are never omitted, and their locations within a word indicate the location of the vowels. The number and location of the dots on a similar-looking letter can change the grapheme it represents. For example, the Arabic letters representing /*t*/ and /*n*/ can become /*th*/ and /*b*/ by changing the number and location of the dots.

Although there is not much research on language disorders involving Arabic speakers, a case study of an Arabic/French bilingual reports symptoms of deep dyslexia in both languages after damage to the left perisylvian region. However, the type of errors made was different in each language. For instance, more semantic errors occurred during picture naming and reading aloud in French than in Arabic. In contrast, there were more translation errors during reading in Arabic (e.g., the Arabic word for 'glasses' was read as the French word for 'glasses'; Beland and Mimouni, 2001).

Laterality research involving the normal Arabic-speaking population is also quite sparse. Studies of letter recognition and letter matching show that Arabic orthography is more difficult than Hebrew orthography, and the pattern of errors is such that Arabic speakers have most difficulty when Arabic letters are presented to the LVF/right hemisphere (Eviatar *et al.*, 2004). In a study using vertical presentation of Arabic CVC stimuli, Arabic–Hebrew bilinguals showed a robust RVF/left hemisphere advantage and a visual field difference in error pattern that was similar to that shown when Hebrew speakers identified Hebrew CVC stimuli. That is, the extent to which the third letter was missed more often than the first letter was larger on RVF/left hemisphere trials than on LVF/right hemisphere trials, just the opposite of English. In addition, averaged across both visual fields, the difference between third-letter and first-letter errors was larger for Arabic than for English or Hebrew. Perhaps the greater orthographic complexity of Arabic combined with the unfamiliar vertical orientation led to more sequential processing being used in both visual fields. Further studies would be useful to examine these possibilities and others.

Farsi

Written Farsi adopted the Nastaliq script in about 1500 A.D. (Hanaway and Spooner, 1995). Nastaliq contains the Arabic characteristics of dots identifying different graphemes and of joining different letters to form a word. Farsi has six vowels, three of which are represented by letters in the word. The other three are represented by vowel markings placed above (two) and below (one) the letters. These marks are used only for beginning readers (similar to literary Arabic and pointed Hebrew), as adults read text without these markings. However, the three letters designating the vowels are never omitted. Whereas stimuli with a fixed letter marking a vowel are linguistically transparent, stimuli with no vowel markings are linguistically opaque. In Farsi, the transparent words are read by using a phonological, nonlexical route, and the opaque words are read by using a lexical route (Baluch and Besner, 1991, 2001).

In one of the only laterality studies using Farsi, Melamed and Zaidel (1993) presented Farsi and English to Farsi–English bilinguals during naming and lexical decision tasks in a visual half-field paradigm. The results revealed a language by visual field interaction, showing the typical RVF/left hemisphere advantage in accuracy and reaction time during naming and lexical decision tasks in English, but no such advantage during naming and lexical decision tasks in Farsi. The authors suggest that the absence of a RVF/LH advantage may indicate greater involvement of the right hemisphere in processing written Farsi, perhaps because of its visual or orthographic complexity or because it is typically scanned from right to left. In any case, the absence of an RVF/LH advantage is sufficiently unusual among the world's alphabetic written languages to warrant replication and extension.

Urdu

Like Arabic and Farsi, Urdu is scanned from right to left, and an important difference from English stems from its orthographic property that clusters of letters together do not make a word (or even a pronounceable nonword) unless they are connected in script-like fashion. Unlike English, there are no distinctions between upper and lower cases in Urdu, but a letter's image may change when it is joined in script with other letters. Designated vowels (a, e, i, o, and u) can be in any position within a word or pronounceable nonword. In some literary and religious texts, vowel markings are used to accentuate spoken vowels. In

everyday Urdu, like Hebrew, Arabic, and Farsi, vowel markings are not used. Urdu self-teaching books designate each unit of sound to one letter. Native speakers employ this letter-by-letter reading strategy as an initial learning technique when they learn Urdu formally. Once basic Urdu is learned, and the patterns of words are understood, this letter-by-letter strategy is abandoned for a more global word-reading technique.

In a series of visual half-field studies, Urdu–English bilinguals were asked to identify sequences of three Urdu letters that were either joined together so as to make Urdu words or pronounceable nonwords or separated so as to be spontaneously processed as individual letters (M. M. Adamson and J. B. Hellige, unpublished data). For both joined and separated words and non-words, there was a RVF/left hemisphere advantage similar to that reported for many other languages. Overall, the third letter was missed more often than the first letter, and this difference was larger for separated letter sequences than for joined letter sequences. This indicates that Urdu letters are processed in a slower, more sequential manner when they are separated than when they are joined to make a word or pronounceable nonword. Visual field differences in the pattern of errors were similar to those found for Hebrew and Arabic and opposite that found for English. Specifically, the tendency for there to be more third-letter errors than first-letter errors was larger on RVF/left hemisphere trials than on LVF/right hemisphere trials. The laterality patterns were identical for words and nonwords, indicating that the effects occur at a prelexical stage of processing (for similar arguments regarding effects in English, see Lindell *et al.*, 2002). The laterality patterns were also similar for joined and separated versions of the stimuli, which may not be surprising in view of the fact that both versions are made up of the same letters, written in the same direction and in the same sequence.

Japanese

The Japanese language system consists of two different types of script: *Kanji*, a logographic form borrowed from Chinese characters, and varieties of the syllabic form of *Kana*, mainly, *Hiragana* and *Katakana*. A Japanese sentence is written by combining all three of these scripts to form different classes of words (Wydell, 2003). Japanese *Kana* has a direct one-to-one relationship between its orthographic representation and its pronunciation. Because of this direct link between phonology and orthography, children learn the *Kana* script very quickly in school (Wydell, 2003). Japanese *Kanji*, however, is taught at junior or high school level. The most striking difference between *Kanji* and *Kana* is that *Kana* depends on the phonological system for its correct pronunciation, and *Kanji* is more dependent on the visual spatial system for correct processing. This is because each *Kanji* character is made up of a morphological element that has no phoneme component or correspondence; that is, a *Kanji* character does not map directly onto any particular phoneme (Wydell, 1998).

Case studies of brain-damaged patients describe the symptoms of phonological alexia in *Kana* and *Kanji* as the inability to read nonwords in both scripts (Patterson *et al.*, 1996; Sasanuma *et al.*, 1996), though it has been suggested that the two scripts use somewhat different neural networks. It is often extremely difficult to compare neuroimaging studies across languages because of differences in various aspects of protocol, including the choice of specific experimental and baseline task demands. Despite these difficulties, a number of studies now indicate that processing of both *Kana* and *Kanji* generally activate the same cortical areas as each other and as are activated in similar studies using English. At the same time, and despite the activation of overlapping cortical regions, it appears that processing *Kanji* involves heavier visual orthographic demands and uses a lexical-semantic system through a more ventral route, involving the inferior occipital, fusiform, and posterior inferior temporal gyri, whereas *Kana* is processed in a more phonetic manner through a more dorsal route, involving temporoparital areas (for elaboration and review, see Thuy *et al.*, 2004).

Behavioral studies using the visual half-field technique have sometimes reported a RVF/left hemisphere advantage for identifying *Kana* words and nonwords, but a LVF/right hemisphere advantage for identifying *Kanji* words and nonwords (Hatta, 1977; Sasanama *et al.*, 1977), leading some to conclude that the left and right hemispheres are superior for processing *Kana* and *Kanji*, respectively (e.g., Coltheart, 1980). It has been suggested that it is the visual complexity of *Kanji* stimuli that leads to more dependence on right-hemisphere processing, with right-hemisphere dominance for visuospatial processing outweighing any left-hemisphere superiority for other stages of processing involved in stimulus identification. In contrast to English, there may not be any laterality effects for lexical decision tasks for *Kanji* (Hatta, 1981), though there is a RVF/LH advantage for lexical decision tasks for *Katakana* and *Hiragana* (Yoshizaki, 2001). A RVF/LH advantage for *Kanji* emerges, however, if the task requires a more semantic judgment (Hatta, 1981).

In a visual half-field field study that required native speakers of Japanese to identify three-letter *Kana* nonwords presented vertically, Hellige and Yamauchi

(1999) found a robust RVF/left hemisphere advantage. Although there were more third-letter errors than first-letter errors, consistent with sequential processing of the letters, this was equally true for both LVF and RVF trials. Hellige and Yamauchi suggest that this may stem from the way in which *Kana* maps on to pronunciation. Specifically, a word or nonword made up of *Kana* characters is pronounced exactly as it is spelled: letter by letter. That is, there is no emergent or unitary pronunciation, as there is in English (D-A-G is pronounced *daeg*), and consequently, less reason for the specialized language mechanisms of the left hemisphere to process the letter sequence in a more holistic way. In addition, *Kana* is most typically scanned from top to bottom, which is quite different from the languages discussed earlier, and this may contribute to the lack of visual field differences in qualitative error patterns.

Chinese

Chinese is a nonalphabetic language with deep orthography (DeFrancis, 1989). Chinese builds its single graphic units from independent strokes, making compound units by incorporating the graphic units in different ways; mainly, left and right, top and bottom, and inside and outside (Perfetti *et al.*, 2002). The main phonetic unit of Chinese Mandarin is a syllable that is further divided into two segments, initial and final. The main script unit is a monosyllabic character representing units of meaning (morphemes). About 90% of Chinese characters (referred to as morphemic) are compound characters having both a semantic and a sound component (Zhu, 1987). Therefore, only 10% of Chinese characters (referred to as pictorial) are exclusively pictographic. The number of strokes in a character can change its phonological or semantic properties (Ho, 2003). Unlike English, recent studies show that reading Chinese involves orthographic-semantic-phonological access at both the word and character levels (Zhang and Perfetti, 1993; Kuo *et al.*, 2001, 2003; Bates *et al.*, 2003). In addition, each character has a phonetic value, but its tone depends on the location within a word, which can then change the meaning (Ho, 2003). In contrast to Chinese, *pinyin* is a completely syllabic script considered to be alphabetic and was created in the 1970s to introduce English words in the mainstream Chinese language. The distinction between *pinyin* and Chinese is similar to the distinction between Japanese *Kana* and *Kanji* and provides interesting opportunities for comparison that are only beginning to be exploited.

Neuroimaging studies indicate that both Chinese and *pinyin* characters activate the same general cortical areas as each other and as are activated in other languages. However, relative activation in some regions differs for these two forms. It has been suggested that activity in some of these regions (e.g., the inferior parietal area for *pinyin* and the fusiform gyrus for Chinese characters) may be associated with reading via assembled phonology (*pinyin*) versus addressed whole-script (Chinese character) procedures (Chen *et al.*, 2002). A variety of additional neuroimaging studies requiring individuals to perform a number of different tasks with Chinese characters is generally consistent with the conclusion that the left inferior frontal gyrus, the left temporoparietal region, and the left temporal-occipital junction are involved in orthographic-to-phonological translation for Chinese, as well as for a number of other languages (e.g., Lee *et al.*, 2004). At the same time, there is some indication that a region within the left middle frontal cortex may be activated in phonological processing of written Chinese but not in processing of most alphabetic languages and that the right hemisphere is heavily involved in reading aloud of Chinese logographs, which also differs from alphabetic languages (e.g., Tan *et al.*, 2001). And the different activation patters found for nouns and verbs in English does not extend to Chinese (e.g., Li *et al.*, 2004). Thus, like alphabetic languages, greater left-hemisphere activation in a number of areas is generally obtained during processing characters and words in Chinese. But, somewhat like Japanese *Kanji*, the subtle differences in neuronal activity echo the differences embedded in the linguistic and visually complex properties of Chinese that make it different from alphabetic languages (for additional neuroimaging studies using a variety of tasks, see Chee *et al.*, 2000; Gandour *et al.*, 2003; Kuo *et al.*, 2003, 2004).

Similar to Japanese *Kanji*, visual half-field studies of Chinese involving normal Chinese speakers reveal a LVF/right hemisphere advantage in word naming and no visual field advantage in a lexical decision task (Tzeng *et al.*, 1979), with this being the case for both pictorial and morphemic Chinese characters (Tzeng *et al.*, 1978; but see Rastatter *et al.*, 1989). As with Japanese *Kanji*, however, a RVF/left hemisphere advantage is found for Chinese when deeper phonological or semantic processing tasks are used (e.g., Leong *et al.*, 1985). In contrast to English, there may not be any word length by visual field advantage for processing Chinese characters, though such an interaction has been reported when the Chinese characters to be identified were embedded in foreign words of different lengths (e.g., Fang, 1994, 1997, 2003) Thus, some aspects of processing Chinese characters and words are qualitatively different from processing English and other languages that more readily show word length by visual field interactions.

General Observations

The foregoing review indicates that there is widespread left-hemisphere superiority for processing printed words and nonwords. This is true for many of the world's languages, and for at least certain aspects of orthographic to phonological mapping, left-hemisphere dominance seems nearly universal. At the same time, printed languages differ in many ways, and there is clear evidence that those differences affect certain aspects of laterality. As examples, consider possible effects related to visual complexity and scanning direction.

One way in which languages differ is in terms of the level of visual complexity represented in printed characters. The right hemisphere is hypothesized to be superior to the left in processing complex visual information outside the language domain. Thus, it would not be surprising to find that the right hemisphere makes a greater contribution to processing texts as they become more visually complex. From this perspective, it may be understandable that the RVF/left hemisphere advantage so typical of letter and word identification in English does not extend to character and word identification in visually complex texts like Japanese *Kanji* and Chinese.

Languages also differ in the direction in which printed material is typically scanned, and this may well have consequences for such things as behavioral measures of laterality. To be sure, RVF/left hemisphere advantages have been reported for left-to-right languages (like English), for right-to-left languages (like Hebrew, Arabic, and Urdu), and for top-to-bottom languages (like Japanese *Kana*). Thus, an overall left-hemisphere advantage for such things as word naming seems sufficiently robust to overcome any effects of scanning direction. However, more subtle qualitative performance differences between LVF/right hemisphere and RVF/left hemisphere trials are more variable across languages and are more likely to be influenced by such things as scanning direction. Consider, for example, the finding reviewed earlier that visual field differences in qualitative error patterns obtained during CVC identification are opposite for English (a left-to-right language) and Hebrew, Arabic, and Urdu (all right-to-left language), and that the qualitative visual field difference is not present at all for Japanese *Kana* (primarily a top-to-bottom language). Of course, we cannot be certain that scanning direction is the only relevant factor in determining these qualitative differences, but the association is nonetheless interesting. In fact, such effects of scanning direction are consistent with a recent model of letter-position encoding that specifies how the habitual scanning direction of a language can produce asymmetric activation patterns across a string of letters and thereby lead to visual field differences in word length and error pattern (Whitney, 2001; Whitney and Lavidor, 2004).

Concluding Comments

In reviews of laterality for language-related processing, it is common to focus on studies that ask native speakers of English to engage in a variety of tasks using English. It is often tempting to generalize the results for English and reach conclusions about laterality for language more generally. Though much has been learned in this way and many of the results obtained with English do, in fact, generalize to many other languages, this review indicates that there are important exceptions, especially in qualitative aspects of processing. Understanding both the generality and the variability in laterality across the world's languages is essential to refining our theories about the brain mechanisms that underlie our ability to understand the spoken and the written word.

History and Affiliations

Latin is an Indo-European language of western central Italy, recorded from about 500 B.C. in the immediate area of Rome, related closely to the poorly attested Faliscan dialect and more distantly to Osco-Umbrian and Venetic. Lexical influences from neighboring languages (Italic dialects, the unrelated Etruscan language, and above all Greek) are visible in Latin from the earliest period. With the rise of Rome, Latin spread throughout Italy and into the provinces of the Roman Empire. It became the spoken language in western continental Europe, displacing the indigenous languages; its spoken varieties developed into the modern Romance languages. A more or less standard version of written Latin remained in use in administration, law, education, and the Church, and in due course spread throughout Europe as Medieval Latin. The status of Latin as a common medium of learned communication began to wane only with the rise of English as a world language in modern times.

Varieties

The dialect of Rome became the dominant form of Latin from an early period, with variations from it being regarded as rustic. Written Latin was standardized by the first century B.C. and remained broadly uniform thereafter, concealing changes and diversification in the spoken idiom; nevertheless a range of literary, technical, or colloquial registers can be distinguished in the surviving texts, and the occurrence of nonstandard written forms can provide evidence for spoken developments. The term *Vulgar Latin* is used to refer to any variety that departs significantly from classical norms. There is no good ground for regarding later written forms – Christian, Medieval, Renaissance, or Modern Latin – as essentially different varieties of the language: despite differences, often quite wide, in orthography, lexicon, style, and pronunciation, they all reflect the same basic linguistic structure and a common if diverse literary tradition. The following approximate periods may be recognized for convenience: Early Latin, to the 2nd century B.C.; Classical Latin, divided into Republican, and Augustan ('Golden'), and Early Imperial ('Silver'), until the 2nd century A.D.; Late Latin (i.e., the Latin of Late Antiquity), 3rd to 6th century A.D.; Medieval Latin, from the 7th to the 13th century A.D., including two high points of Latin culture, the Carolingian period (9th century) and the 12th-century renaissance. The term *Neo-Latin* embraces Renaissance Latin (14th to 15th centuries), the scholarly and scientific Latin of the early modern period, and modern uses of the language.

Script

The Latin alphabet, the basis of current Western European alphabets, was derived from a form of Greek script introduced into Italy by colonists from Euboea. In its classical form, it contains all the letters that are still used in Modern English except for J, U, and W; V (the U shape developed later) was used for the vowel /u/ and the semivowel /w/; I was used for the vowel /i/ and the semivowel /j/. Y and Z, originally absent from Latin, were imported for use in Greek borrowings. The capital letters, used for inscriptions, have retained their classical form more or less unchanged. Originating in Roman cursive, a variety of handwritten styles evolved from late antiquity onward and ultimately gave rise to modern lowercase letters.

The term *Neo-Latin* embraces Renaissance Latin (14th to 15th centuries), the scholarly and scientific Latin of the early modern period, and modern uses of the language.

Script

The Latin alphabet, the basis of current Western European alphabets, was derived from a form of Greek script introduced into Italy by colonists from Euboea. In its classical form, it contains all the letters that are still used in Modern English except for J, U, and W; V (the U shape developed later) was used for the vowel /u/ and the semivowel /w/; I was used for the vowel /i/ and the semivowel /j/. Y and Z, originally absent from Latin, were imported for use in Greek borrowings. The capital letters, used for inscriptions, have retained their classical form more or less unchanged. Originating in Roman cursive, a variety of handwritten styles evolved from late antiquity onward and ultimately gave rise to modern lowercase letters.

Phonology

Sound/Spelling Relationship

The Classical Latin alphabet represents the sounds of the language quite well, except for its failure to distinguish the semivowels (as we now distinguish, e.g., *voluit* 'he wanted' from *volvit* 'he rolls'). Phonemic doubling of consonants was usually but not invariably indicated. In the classical period, vowel length was shown sometimes by doubling the vowel, more often by means of the *apex*, a diacritic resembling the acute accent. In Latin as conventionally printed, vowel length is not regularly indicated; so, for example, *canis* can represent either *cănĭs* 'dog' or *cānīs* 'grey hair (dative-ablative)'.

A number of sounds initially caused spelling difficulties: (a) Classical Latin had a series of nasal vowels, represented (consistently with etymology) by vowel + *m* finally and vowel + *n* medially; (b) a vowel sound midway between /i/ and /u/ was found in words such as *optumus/-imus* 'best' and other superlatives, and *lubens/libens* 'willing'; (c) there was no separate symbol for the velar nasal (see note *c* under the following consonant table).

Consonants

The consonantal inventory of Latin may be set out as follows:

	Labio-velar	*Velar*	*Dental*	*Labial*
Voiceless stop	/k^w/ <qu>	/k/[a] <c>/ <k>	/t/	/p/
Voiced stop	/g^w/ <gu>[b]	/g/	/d/	/b/
Nasal		/ŋ/ <n>/ <g>[c]	/n/	/m/
Fricative	glottal: /h/	alveolar: /s/		labiodental: /f/
Liquid		rolled/ flapped: /r/ lateral: /l/[d]		
Semivowel		palatal: /j/ <i>		labial: /w/ <u>/<v>[e]

[a]The original sound was /k/, but the Romance and Medieval palatal realization before front vowels may already have started to develop in antiquity.

[b]Occurs only medially after a nasal or liquid as in *languidus* 'languid', *urgueo* 'press'.

[c]Occurs only medially, (a) as the outcome of /n/ before a velar, or (b) as the outcome of /c/ or /g/ before a nasal; written in the first case as <n>, as in *tango* 'touch', and in the second as <g> as in *dignus* 'worthy' (< **dec-nos*, cf. *dec-ens* 'decent'). The combination /ŋn/ <gn> later underwent a further sound change to palatal /ñ/, found, for example, in Italian.

[d]Represented by both 'clear' and 'dark' (velarized) allophones, as shown by the effect on neighboring vowels.

[e]The sound /w/ later changed to /β/ or /v/; spelling variations indicate that this took place (under Greek influence?) in Italy and the East possibly as early as the first century A.D., and in the western provinces at a later period.

Vowels

Classical Latin had a symmetrical five-way vowel system with phonemic distinction between long, short, and nasalized vowels: e.g., *puellă* 'girl' (nominative): *puellā* /-a:/ (ablative): *puellam* /-ã/ (accusative). Early Latin had a range of inherited diphthongs, which were considerably simplified by the Classical period; further leveling took place in varieties of the spoken language (*au* > /o:/, *ae* > open /ę:/, *oe* > /e:/), giving rise to confusion in spelling. In Romance, the classical vowel system was remodeled: nasalization and phonemic vowel length disappeared, while changes in vowel quality led to merger of short /i/ with long /e:/, and of short /u/ with long /o:/.

Accent and Prosody

Classical and post-Classical Latin has a largely predictable stress accent: the accent falls on a long penultimate, but on the antepenultimate if the penultimate is short. (A short syllable is an open syllable containing a short vowel; all other syllables, except for a few doubtful cases, are long.) This had apparently replaced an earlier initial stress accent, which is postulated to account for the regular vowel weakening that took place in early Latin in non-initial syllables, e.g., *pro* 'before' + *habeo* 'hold' > *prohibeo* 'forbid'. The usually clear distinctions of syllabic quantity made it possible for quantitative meters borrowed from Greek to replace the native 'Saturnian' verse form. Stress accent plays no formal part in Classical Latin verse, although there is an interaction between quantitative rhythm and word accent, which both creates some metrical restrictions and allows for considerable poetic subtlety. Stressed rhythms were reintroduced in Late and Medieval Latin.

Morphology

Inflection

Latin is an inflected language retaining a number of features of the parent Indo-European, but with considerable innovation, especially in the verbal paradigm.

Nouns are inflected for number and case. There are two numbers, singular and plural, and five regular cases: nominative, accusative, genitive, dative, and ablative. Nouns are traditionally grouped in five declensions: the first and second declensions continue the IE O/A stems, the third and fourth continue the IE stems in consonants and semivowels, and the fifth is a Latin innovation of mixed origin. A separate vocative is found only in the second declension and in borrowed Greek names. A locative case exists in place

names and in a few common nouns, such as *domi* 'at home' from *domus* 'home'. Nouns are assigned to one of three gender categories – masculine, feminine, and neuter – on the basis partly of sense and partly of form, so that on the whole there are fewer unpredictable or illogical assignments of gender than in many other languages.

Adjectives, both as attributes and as complements, agree with nouns in gender, number, and case; they broadly follow the same patterns of declension as nouns. There are no articles, but there is a rich pronominal system including four demonstratives (*is* 'the one mentioned', *hic* 'this', *iste* 'that of yours', *ille* 'that over there') and a distinction between specified and nonspecified indefinite pronouns (*quidam* 'someone in particular', *aliquis* 'someone or other').

Verbs are inflected according to the person and number of the subject. Subject pronouns are regularly dropped (*amamus* 'we love'). There are two sets of personal endings, indicating voice: active *-o/-m -s -t -mus -tis -nt*, passive *-r -ris/-re -tur -mur -mini -ntur*; and one other set of endings peculiar to the perfect active. Verbs are classified in four conjugations according to stem vowel. The principal parts of a Latin verb, from which all other forms can be derived, are the first person singular present indicative active (normally listed in the dictionary, e.g., *dico* 'I say'), the present infinitive active (e.g., *dicere* 'to say'), the first person singular perfect active (e.g., *dixi* 'I said'), and the past participle passive (e.g., *dictum* 'said'). The stems of the present and perfect are combined transparently with tense markers to form two further indicative tenses and two subjunctive from each stem, e.g., *procedeba-m* 'I was proceeding' (imperfect indicative), *praedix-era-tis* 'you had predicted' (pluperfect indicative), *mane-re-mus* 'we would be staying' (imperfect subjunctive), *decipi-a-mini* 'you would be deceived' (present subjunctive passive). There are two imperatives, one used for immediate commands (*exi!* 'get out!'), the other for instructions (*bene misceto* 'mix well'). The perfect tenses of the passive are formed periphrastically: the past participle is combined with an appropriate (present-stem) form of *esse* 'be', e.g., *occisa est* 'she has been killed'.

A restricted class of verbs (generally known as 'deponents': fossilized remnants of the old middle voice) take passive morphology although their meaning is active and can be transitive: e.g., *philosophor* 'I philosophize'; *vereor* (transitive) 'I fear'. Intransitive active verbs (including a class of verbs that take a dative object) have no passive, except third-person singular forms used impersonally, e.g., *venio* 'I arrive'; *venitur* 'people arrive' (cf. the impersonal passive in the Celtic languages). Genuinely irregular verbs are few (*sum* 'be', *possum* 'can', *volo* 'want', and some others). The greatest difficulty in Latin verbal morphology is the often unpredictable formation of the perfect stem.

The verb has two infinitives, present (*dicere* 'to say') and perfect (*dixisse* 'to have said'); other verbal nouns (gerunds, supines) supply case forms for the infinitive. There are three participles, present active (*dicens* 'saying'), past passive (*dictum* 'said'), and future active (*dicturus* 'about to say'), and a verbal adjective (the gerundive), which is future passive in meaning and often denotes obligation (*faciendum est* 'it is to be done').

Derivational Morphology

Latin has a productive system of derivational morphology, much of which is familiar through derivatives in modern languages, e.g., prepositional prefixes such as *ex-* 'out', *circum-* 'round'; other prefixes such as *in-* 'not', *re-* 'back', nominal suffixes such as *-tio(n)-* (process) and *-tor* and *-trix* (male and female agents), and adjectival suffixes such as *-bilis* (*inextricabilis* 'inextricable'), *-anus* (*Christianus* 'Christian'), *-arius* (*piscarius* 'to do with fish'). Adjectives form adverbs (in *-e*, *-o*, or *-ter*), comparatives in *-ior*, and superlatives in *-issimus*. At first, Latin was resistant to some kinds of derivation; for example, compound nouns or adjectives were relatively unusual, occurring mostly in high style (*solivagus* 'wandering alone') or as comic colloquialisms (*caldicerebrius* 'hot-headed'). From the classical period onward, the need to express new ideas led to a large expansion of the classical lexicon both by derivation and by borrowing.

Syntax

Word Order

Because Latin encodes basic grammatical relations by means of inflection, there is considerable freedom in word order. Either a topic or an emphasized predicate may be placed first in a sentence, and variations of logical emphasis are also common at phrase level. Classical Latin preserves the Indo-European phenomenon known as Wackernagel's Law, i.e., the first stressed position in a sentence or clause is followed by an unstressed position which often contains, in order of precedence, (a) sentence connectives, (b) weak pronouns, (c) unstressed verbs. The phenomenon of hyperbaton, or discontinuity in the noun phrase, is a particular feature of Latin as it is of Classical Greek: its effect is often to

throw particular focus on to the first element of the noun phrase, e.g.:

bonos	*habemus*	*consules*
good-MASC.ACC.PL.	we-have	consuls-ACC.PL.
+ Focus		
'we have *good* consuls'		

Because of inflection, the absence of articles, and the flexibility of word order, Latin is capable of considerable compression, hence the lapidary style favored in inscriptions, proverbs, and epigrams.

Complex Sentence Structure

Subordination is much favored in varieties of literary Latin; Classical Roman writers influenced by the Greek periodic style made full use of the available syntactical resources, e.g., the inflected relative pronoun enabling any nominal constituent to be relativized, and the free use of the accusative-infinitive construction to create continuous indirect speech (*oratio obliqua*), as well as paratactic devices such as apposition, parallelism, ellipsis, and chiasmus. Means were found to compensate for the lack of certain features (e.g., the past participle active) which had made for flexibility in Greek, and the rich tense system is fully exploited in classical narrative prose. Late and Medieval Latin usage often blurs the distinctions of tense and mood found in Classical Latin; the conjunction *quod* 'that' gains ground at the expense of the accusative-infinitive, the active present participle becomes more frequent, and the periphrastic constructions characteristic of the Romance verbal conjugation begin to appear.

Ancient and Medieval Lexicography

Roman contact with the Greek world and familiarity with Greek scholarship led to the creation of bilingual Greek–Latin and Latin–Greek word lists and dictionaries for practical and educational uses in the classical period. Monolingual Latin lexicography can be seen in the few works that have survived, e.g., that of Nonius, a grammarian of the 3rd and 4th centuries, and Isidor, bishop of Seville (7th century), in the tenth book of his encyclopedia *Etymologiae*. Verrius Flaccus' work, *De verborum significatu,* is preserved in an abridged version by Festus and was further shortened by Paulus Diaconus. Furthermore, glossaries, mostly anonymous, served educational purposes, explaining difficult words in literature. One of the most important collections is the *Liber glossarium* (8th century). In early medieval times this served as input for two important works, Papias' *Elementarium* (11th century) and Osbern of Gloucester's *Derivationes* (12th century). These two were the precursors of late medieval lexicography as manifested in the *Liber derivationum* by Hugutio and the *Catholicon* by Johannes Januensis.

Modern Latin Lexicography

During the Renaissance much lexicography was devoted to explaining Latin terms in the various vernacular languages of Europe. Two major monolingual Latin lexicographic works appeared. The *Dictionarium* (1502) by Ambrosius Calepinus, the Augustinian monk of Bergamo, was innovative in that the etymology was seen as secondary to the explanation of meanings. Even more importantly, examples of the uses of words are given. Calepinus made a second edition, and after his death his dictionary was revised and reprinted many times. In Paris, Robertus Stephanus (Robert Estianne)'s plan to produce a new edition of Calepinus resulted in a totally new dictionary in 1531, the *Dictionarium seu Latinae linguae thesaurus*, based on Calepinus and on citations from literature. The French glosses were removed in the revised edition (1536) to make room for a huge amount of additional Latin material. This led to the first compendious Latin monolingual dictionary, which remained the authority until the late 18th century.

A new era of Latin lexicography was inaugurated by Egidio Forcellini's *Totius latinitatis lexicon* (1771), which offers a huge collection of materials. An innovative contribution was the internal structure of the entries: Forcellini distinguished strictly between different meanings by exhibiting the relation between the core meaning and the derived meanings of a word (e.g., figurative usage). This dictionary, which also takes account of inscriptions, was abridged and revised by many scholars and was the basis for most 19th-century dictionaries. The abridgment by Wilhelm Freund (1834–1835) served as foundation for the dictionary by E. A. Andrews (1850), which in turn was revised and reedited by Charlton T. Lewis and Charles L. Short (1879).

The project *Thesaurus linguae Latinae (TLL)*, now hosted by the Bavarian Academy of Sciences in Munich, is compiling a scholarly dictionary that covers all of existing Latin literature from the beginnings until 600 A.D. The first fascicle was published in 1900; by 2004, the word *propositio* had been reached. P. G. W. Glare's *Oxford Latin dictionary* (1968–1975) is the most extensive and complete dictionary available today. It includes literary, epigraphic, and other sources. Still valuable is K.-E. Georges' *Ausführliches lateinisch-deutsches Handwörterbuch* (revised by H. Georges, 2 vol., 1913–1918, reprinted in 1988). The Perseus Project at Tufts University is an online dictionary with English metalanguage based on Lewis and Short.

Medieval Latin

A largely neglected area of Latin scholarship, medieval Latin was first treated by Du Cange's *Glossarium mediae et infimae latinitatis* (1678), which covers the period from 800 to 1200 and is still used as a reference for later Latin. The project *Das mittellateinische Wörterbuch*, hosted at the Bavarian Academy of Sciences, covers the whole vocabulary of medieval Latin (even words that occurred already in antiquity). It covers the period from 600 A.D. (where the *TLL* stops) until 1280. The definitions are given in German. By 2004 the work had reached the word *dominum*.

Etymological dictionaries

The two most authoritative etymological dictionaries of Latin are the *Dictionnaire étymologique de la langue latine* (1932, fourth edition 1959) by Alfred Ernout and Antoine Meillet and the *Lateinisches*

etymologisches Wörterbuch by Alois Walde (1906), revised by Johann B. Hofmann (third edition 1954–1956).

Latvia: Language Situation

I Druviete, University of Latvia, Riga, Latvia

Latvia [Latvija] is one of the three Baltic states. Its territory covers about 64 000 km^2. It has approximately 2 309 000 inhabitants. The Republic of Latvia was founded in 1918; its independence was renewed in 1991. In March 2004 it joined NATO, and as of May 1, 2004, it is a full member of the European Union.

Around 3000 B.C., the Finno-Ugric Livs settled there. During the first half of the next millennia, the ancient Baltic tribes arrived. The formation of the common Latvian language began during the 10th to 12th centuries A.D., when German crusaders conquered the territory. In the 16th century, the Livonian nation collapsed and today's Latvian territory fell into the hands of the Polish-Lithuanian Commonwealth until the Polish-Swedish War. After the Great Northern War (1700–1721) today's Latvian territory became part of the Russian Empire. In 1918, Latvia declared its independence. On June 17, 1940, Latvia was occupied by the Soviet Army. Latvia was again recognized as an independent state on August 21, 1991.

The ethnic composition in Latvia is as follows: 58.7% Latvians, 28.8% Russians, 3.9% Belorussians, 2.6% Ukrainians. 2.5% Poles, 1.4% Lithuanians, 0.4% Jews, 0.3% Roma, 0.2% Germans, 1.2% others (2004 Civil Data Register).

The Latvian language belongs to the Baltic group of the Indo-European family of languages. It is spoken by approximately 1.55 million people in Latvia and abroad as the first language and by approximately 500 000 people in Latvia as the second language. Typologically, Latvian is an inflectional language. The first written texts in Latvian appeared in the 16th century.

The Latvian language is the official language in the Republic of Latvia. The Law on the State Language (1999) is in force now. Ethnic minorities have the right to preserve and develop their language and their identity. The state finances primary education in eight languages.

The Liv language has a particular status of the only autochthonous minority language. Though about 170 people consider themselves Livs today, there are only five native speakers left.

The Russian language is the native language for 665 000 Russians, due to Russification processes for 72.8% Belorussians, 67.8% Ukrainians, and 57.7% Poles in Latvia. The first Russian settlers came to Latvia during 16th and 17th centuries. In 1935, 8.8% of the population in Latvia were Russian; during the Soviet period the number of Russians increased more than four times. Russian now is the language of tuition for 30% of all students. Apart from the publications brought from Russia, 70 local newspapers are on offer. Several TV channels and radio stations broadcast in Russian.

The Polish language was widespread in the eastern part of Latvia, yet today its role has diminished. Of the 60 000 Latvian Poles, only 11 500 recognize it as their native language. There are six Polish schools in Latvia. The Belorussian language is known by 36 000 Latvian residents, yet it is rarely used at home. There is one Belorussian school in Riga with about 100 students. Ukrainians mainly entered Latvia after World War II. The Ukrainian secondary school has about 300 students. Small Estonian, Lithuanian, and German communities have active cultural lives. Romany in Latvia has a particular dialect. A language primer and various books have been published in it.

Latvian

S Young, University of Maryland Baltimore County, Baltimore, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

Latvian (*latviešu valoda*), with some 1.5 million speakers in the Republic of Latvia, is one of two present-day Indo-European Baltic languages, the other being the structurally more conservative Lithuanian. The Latvian standard language is based on the central Latvian dialect (*vidus dialekts*), which is further divided (from west to east) into Couronian, Zemgalian, and Vidzeme varieties. The central dialect, together with Tamian in northwestern Couronia and along the northeastern coast of the Bay of Riga, is known as Low Latvian. High Latvian (Selonian and Latgalian, the latter with an independent literary tradition), is found in the eastern third of the country.

The traditional view of the origin of Latvian is that it represents a synthesis of the language of the early Latgalians (known from the 13th century on simply as *Letti*, that is, Letts or Latvians) and neighboring closely related Baltic dialects, now extinct, among them Zemgalian (along the Lielupe river), Couronian (in southwestern Latvia), and Selonian (along the middle Daugava). The influence of these Baltic substrata, together with that of Balto-Finnic and Slavic neighbors, accounts in large part for the marked

Latvian (*latviešu valoda*), with some 1.5 million speakers in the Republic of Latvia, is one of two present-day Indo-European Baltic languages, the other being the structurally more conservative Lithuanian. The Latvian standard language is based on the central Latvian dialect (*vidus dialekts*), which is further divided (from west to east) into Couronian, Zemgalian, and Vidzeme varieties. The central dialect, together with Tamian in northwestern Couronia and along the northeastern coast of the Bay of Riga, is known as Low Latvian. High Latvian (Selonian and Latgalian, the latter with an independent literary tradition), is found in the eastern third of the country.

The traditional view of the origin of Latvian is that it represents a synthesis of the language of the early Latgalians (known from the 13th century on simply as *Letti*, that is, Letts or Latvians) and neighboring closely related Baltic dialects, now extinct, among them Zemgalian (along the Lielupe river), Couronian (in southwestern Latvia), and Selonian (along the middle Daugava). The influence of these Baltic substrata, together with that of Balto-Finnic and Slavic neighbors, accounts in large part for the marked

dialectal diversity of Latvian within a relatively small territory.

The beginnings of a Latvian literary tradition date to the Reformation. The first published book in Latvian is a 1585 translation of a Catholic catechism; this was soon followed by other religious texts, chiefly translations. The language of these early texts is to varying degrees influenced by the German speech of the authors, especially in syntax. Efforts to establish a national standard language were begun in the mid-19th century; the Latvian traditional folksongs (*dainas*) served as an important source of norms for the standard language. A milestone in the codification and description of modern Latvian was the appearance of Jan Endzelin's (Jānis Endzelīns) *Lettische grammatik* (1922) and the four-volume *Latviešu valodas vārdnīca* [*Dictionary of Latvian*] (1923–32), begun by Karl Mühlenbach (Kārlis Mīlenbahs) and completed by Jan Endzelin.

The Latvian vowel phonemes include /i, u, ɛ, æ, a/ (spelled *i, u, e, e, a*) and their long counterparts /iː, uː, ɛː, æː, aː/ (spelled *ī, ū, ē, ē, ā*). In addition, a long and short *o* are found in borrowed words. The vowels /ɛ/ and /æ/ (and /ɛː/ and /æː/) are represented in writing by a single *e* (*ē*), reflecting the fact that they are derived from a single source, Baltic *e* (**ē*). Originally conditioned by the nature of the following vowel, they now function as separate phonemes. Functioning as long vowels are the diphthongs [i͡ɐ, u͡ɐ] (written *ie, o*), which result from Common Baltic **ei* and **ō*: *dìevs* 'God' (**deiu̯-*), *nò* 'from' (**nō*), and from tautosyllabic sequences *en* and *an*: *pìeci* [pi͡ɐt͡si] 'five,' *ròka* [ru͡ɐka] 'hand' (Li. *penkì, rankà*). In final syllables Baltic long vowels are shortened and short *e* and *a* are lost: La. *vìlks* 'wolf': Li. *vilkas*.

Among the consonants of Latvian, the obstruents reflect a voiced:voiceless opposition, with regressive voicing assimilation (*atbilde* ['adbilde] 'answer,' *labs* [laps] 'good'); unlike Lithuanian, word-final consonants in final position are not devoiced: *kad* [kad] 'when.' Latvian lacks the feature of palatalization found in Lithuanian, but distinguishes a series of palatal consonants: *ķ* [c], *ģ* [ɟ], *ņ* [ɲ], *ļ* [ʎ]; *ķ* and *ģ* are found mainly in borrowed words. Characteristic of the Latvian consonant system is the development of *t͡s*, *d͡z* from Baltic *k, g* before a front vowel: *cits* 'other' (Li. *kìtas*), *dzìmt* 'to be born' (Li. *gimti*). The Baltic reflexes of the IE palatovelars have merged in Latvian with *s* and *z*: *sìmts* 'hundred' (Li. *šimtas*) < IE **ḱm̥tó-*, *zeme* 'earth' (Li. *žemė*) < IE **d^{h}ǵ^{h}em-*. Secondary palatals *ʃ, ʒ* (orthographically *š, ž*) have arisen in turn from the sequences **si̯*, **ti̯* (>*ʃ*) and **zi̯*, **di̯* (>*ʒ*) before a back vowel: *šũt* 'to sew' (<**si̯ūt-*).

With a few exceptions, Latvian has initial stress. The standard language distinguishes three phonemic tones (marked only in linguistic texts) on long vowels and diphthongs: level [˜] and broken [ˆ], both representing Baltic acute tone; and falling [`], representing Baltic circumflex: *mît* 'to tread,' *mît* 'to change (arch.),' *mìt* 'resides.' Only the central Latvian Vidzeme dialect around Valmiera still distinguishes all three such tones; remaining dialects oppose only two (outside of High Latvian, broken and falling tone typically merge as either falling or broken tone).

The Latvian noun distinguishes masculine and feminine gender, each with three declensional patterns. Within declensional paradigms, five cases are distinguished morphologically: nominative, genitive, dative, accusative, and locative, in both the singular and plural. Adjectives, which occur in both definite and indefinite forms, agree with the noun in number, gender, and case.

The Latvian verb distinguishes present, past, and future tenses, and has a system of relative tenses formed with *būt* 'to be' and the past active participle. The verb has three conjugational types (only two of which are productive), each with a number of subtypes. The 1 sg. present and past forms coalesce in many instances where the stems are not distinguished by root vowel gradation. Like Lithuanian, singular and plural are not distinguished morphologically in the third person.

Peculiar to Latvian, from a Baltic perspective, is the syntactic construction *man ir* 'to-me is' for 'I have' (Li. *aš turiù*) and the use of the debitive (expressing obligation), formed with the particle *jā-* and the 3rd person present, with a dative subject: *man jābrauc* ("to-me must-go") 'I must go.' Like Lithuanian, Latvian uses a preposed adnominal genitive: *latviešu valoda* ("of-Latvians language" = 'Latvian language').

The lexicon has been rather strongly influenced by neighboring Baltic Finnic languages, chiefly Livonian: interrogative particle *vài* (Liv. *või*), *mãja* 'house' (Est. *maja*); and also by German: Middle Low German during the Hanseatic period and New High German thereafter (*brīvs* 'free': MLG *vrī, ùn* 'and': MLG *un*, *briĩles* 'eyeglasses' NHG *die Brille*). Nevertheless, Latvian preserves a number of Indo-European archaisms not found elsewhere in Baltic: *asins* 'blood,' *agrs* 'early.'

Latvian Lexicography

A Veisbergs, University of Latvia, Riga, Latvia

© 2006 Elsevier Ltd. All rights reserved.

Latvian lexicography has been and remains primarily bilingual. This has been historically determined by the dominance of one or another country in the region – so that dictionaries accommodated to the situation accordingly. It is usual to date Latvian lexicography from 1638, when G. Mancelius's *Lettus* was published, containing about 6000 German-Latvian entries. There were also two multilingual dictionaries published in the same century: a Polish-Latin-Latvian work by Elger (1683) and a German-Latin-Polish-Latvian one by Dressel (1688). The following two centuries saw the same pattern – although the dictionaries increased in size and quality, they were made by non-Latvians. The situation changed in the middle of the 19th century, when after the national 'awakening' Latvian linguists took hold of lexicography. The new dictionaries were purged of German and Russian loanwords, and they came closer to spoken language yet also became more prescriptive, the Waldemahr (1872), with 50 000 entries. The dictionary scene up to 1900 was thoroughly researched by Zemzare (1961).

The iconic Latvian dictionary of the 20th century is the four-volume work by Muehlenbach and Endzelins, published in 1923, with supplements appearing in 1932 and 1946. It contains a wealth of Latvian word-stock, though purged of later loanwords. The dictionary contains roughly 120 000 entries in the new orthography with explanations (in German), etymologies, stress patterns, citations, and examples and, despite the passage of time and several shortcomings, it is still viewed as the 'proper' source of Latvian lexis.

The beginning of the 20th century saw an expansion of bilingual dictionaries in the new contact languages – English and French – as well as a strong emphasis on dictionaries of foreign words. The Soviet period produced the first extensive monolingual explanatory dictionary of literary Latvian (*Latviešu literārās valodas vārdnīca*) in eight volumes, which, however, suffers from a lack of colloquial language and is affected by ideological constraints. A one-volume desk dictionary (25 000 entries) of standard Latvian, *Latviešu valodas vārdnīca*, was published in 1987 and has been reprinted several times.

Bilingual lexicography in Latvian is fairly advanced, with relatively big new dictionaries covering not only the traditional contact languages such as English, Russian, and German, but adding Estonian, Italian, Lithuanian, Polish, Spanish, and in the 1990s also Scandinavian and some Eastern languages. The last decade has seen the creation of new Latvian-English (Veisbergs, 2003), English-Latvian (2004), and French-Latvian (Auziņa, 2001) dictionaries as well as older German-Latvian and Russian-Latvian dictionaries reprinted and updated.

Among other important contemporary lexicographical sources one should mention dictionaries of etymology (Karulis, 1992), foreign words (Baldunčiks, 1999), idioms (Laua *et al.*, 1996), dialects, spelling, pronunciation, toponyms, abbreviations, numerous terminology dictionaries, and foreign name-spelling dictionaries (Latvian uses transcription for rendering foreign proper nouns).

Electronic Resources

Latvian lexicography suffers from the lack of a proper corpus. Other electronic tools are fairly well developed. A combination of various bilingual dictionaries is available from Tilde, and some of Tilde's resources are available on the Internet. An up-to-date and comprehensive Latvian explanatory dictionary with electronic access is being slowly built. Other portals include Valsts Valoda, the state language commission, and Valsts Valodas Aģentūra, the state language agency.

Various language-related resources, including Muehlenbach and Endzelins's dictionary, can be found on the website of the Artificial Intelligence Laboratory in the University of Latvia's Department of Mathematics and Computer Science. Termnet offers

Law and Language: Overview

D Kurzon, University of Haifa, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Interest in legal language is not a modern phenomenon, although extensive research into it began to appear only in the latter part of the 20th century. Earlier comments on the language of law were exclusively critical of the style, vocabulary, and structure of legal texts, especially legislative language. We find the French philosopher Baron de Montesquieu in his *De l'Esprit des Lois* (1748) arguing for a simple legal language, to be understood by all readers in the same way, and furthermore to be understood by people even of mediocre understanding ("*de mediocre entendement*"). The 19th century English utilitarian, Jeremy Bentham, also proposed that legislation should be written in a language understood by laypersons. "Clearness in respect of its language" was one of the seven properties, Bentham argued, "a body of law . . . must be possessed of."

These comments show that there was a problem felt by leading thinkers concerning the language of the law. Both Montesquieu and Bentham related to legislation, but their criticism may be equally directed to other legal documents. Furthermore, legal language and legal institutions have been the target of criticism in literature. Charles Dickens' description of the English Chancery Court in his novel *Bleak House* – the time it takes for the judges to decide a case, the language which no one understands, etc., – is well known.

In the early days of modern linguistics, before it had become an established discipline, we do find studies on the law and its language. Several members of the pre-World War II Prague Linguistic Circle addressed problems of legal language. The language of legislators was examined from a functional perspective, with the focus on the educational level of readers of legislative texts, which implies that many people who are affected by the law are not able to read the texts in which the law is written. Another facet of the work of Prague linguists was in the field of vocabulary; observations were made on the careful use of words in legal texts which have inexact meanings in everyday discourse.

Academic lawyers had also dealt with legal language, and published articles, and even textbooks on the drafting of legislation and other documents. These tend to be prescriptive from a lawyer's point of view, and are not outwardly critical of the structural complexities found in legal texts. An exception is the seminal work of David Mellinkoff (Mellinkoff, 1963),

access to terminology containing various sources of language combinations from various times. The website of Tulkošanas un Terminoloģijas Centrs (Translation and Terminology Center) contains material dealing with EU matters.

Law and Language: Overview

D Kurzon, University of Haifa, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Interest in legal language is not a modern phenomenon, although extensive research into it began to appear only in the latter part of the 20th century. Earlier comments on the language of law were exclusively critical of the style, vocabulary, and structure of legal texts, especially legislative language. We find the French philosopher Baron de Montesquieu in his *De l'Esprit des Lois* (1748) arguing for a simple legal language, to be understood by all readers in the same way, and furthermore to be understood by people even of mediocre understanding ("*de mediocre entendement*"). The 19th century English utilitarian, Jeremy Bentham, also proposed that legislation should be written in a language understood by laypersons. "Clearness in respect of its language" was one of the seven properties, Bentham argued, "a body of law . . . must be possessed of."

These comments show that there was a problem felt by leading thinkers concerning the language of the law. Both Montesquieu and Bentham related to legislation, but their criticism may be equally directed to other legal documents. Furthermore, legal language and legal institutions have been the target of criticism in literature. Charles Dickens' description of the English Chancery Court in his novel *Bleak House* – the time it takes for the judges to decide a case, the language which no one understands, etc., – is well known.

In the early days of modern linguistics, before it had become an established discipline, we do find studies on the law and its language. Several members of the pre-World War II Prague Linguistic Circle addressed problems of legal language. The language of legislators was examined from a functional perspective, with the focus on the educational level of readers of legislative texts, which implies that many people who are affected by the law are not able to read the texts in which the law is written. Another facet of the work of Prague linguists was in the field of vocabulary; observations were made on the careful use of words in legal texts which have inexact meanings in everyday discourse.

Academic lawyers had also dealt with legal language, and published articles, and even textbooks on the drafting of legislation and other documents. These tend to be prescriptive from a lawyer's point of view, and are not outwardly critical of the structural complexities found in legal texts. An exception is the seminal work of David Mellinkoff (Mellinkoff, 1963),

Language of the Law. In his book, Mellinkoff, a lawyer, is highly critical of the obtuse language lawyers employ in their documents.

Fields of Research

This section introduces the various fields of research that have grown over the past 30 years or so. Reference will also be made to the various articles that appear in this encyclopedia that relate to current research into those fields of law and language.

Linguistic interest in the language of the law was perhaps initiated by David Crystal and Derek Davy in their book on *Investigating English style* (Crystal and Davy, 1969). In this work, the authors examine a number of registers of English, including the legal register. In the chapter on legal language, they deal with the language of contracts, pointing out the style of legal draftsmen who have developed an intricate and syntactically complex style, in order, on the one hand, to prevent misunderstanding, and on the other, to cover all what the clients want to say and not to depend on extrinsic evidence for the interpretation of the document. They draw attention especially to (1) the conditional structure of the legal sentence; (2) the placing of modifiers immediately adjacent to the phrase or word to be modified; (3) the use of nonfinite clauses as postmodifiers; and (4) the lack of explicit connection between the sentences of a document with its accompanying repetition of lexical items and the accompanying sparing use of pronouns. Following Crystal and Davy's book came a spate of work on legal language, especially the language of legal documents. A great deal of this work has been in the fields of grammar, especially syntax, and lexis. Much of the research was produced by Scandinavian scholars (e.g., Gustafsson, 1975), and several of the papers in the special issue of *Text* (1984) were devoted to the language of legal documents (*see* **Language of Legal Texts**) deals directly with written legal language, while other articles have a bearing on this register (*see* **Law on Language**).

In the United States, interest in the law and language came initially more from a sociological and anthropological than a linguistic perspective. One may also cite work on the language of Barotse jurisprudence, Yakan litigation, and Shawnee laws, among others. The type of doubletalk and gobbledygook used by government during the Vietnam War and especially during the Watergate affair also led to many researchers putting the focus on the language of administration and of law. Only in the early 1970s were sociolinguists introduced to this area of research. Brenda Danet's overview of language in the legal process, which appeared in the *Law and Society Review* in 1980, served as a stimulus to further and broader research in the areas of law and speech. Interest in oral communication in Western legal cultures grew, too, with the development of more efficient recording equipment, which allowed a more accurate record of spoken legal proceedings, thus allowing linguists and conversational analysts to tackle courtroom discourse. A conference was held in 1985 at Georgetown University on spoken legal discourse, e.g., witness questioning, depositions, jury instructions and interpretation; many of the papers presented were published by Levi and Graffam Walker (1990). Another research field in the area of law and spoken language addresses lawyer–layperson communication. This involves dialogue not only in the courtroom but also in the lawyer's office when the lawyer speaks to his/her client.

It can be seen that this distinction between written and spoken legal language is one that pervades research into legal language. Taxonomies of types of legal language have been set up. Within the mode of written legal language, not only are documents such as legislation and contracts examined, but also legal textbooks and law reports. Spoken legal language may be subcategorized into courtroom discourse and out-of-court discourse, and each of these subcategories may be further subdivided; see a description of genres in general (*see* **Legal Genres**).

Against the background of growing interest in spoken legal language, the study of written legal language may seem to have reached its peak in the 1980s; further work on legislative texts, on contracts, and on wills has been carried out not so much from a structural point of view, but more from a discourse and pragmatic perspective. Legal texts, especially written legal documents, have been analyzed as discourse. Moreover, pragmatics has been extended to speech in legal proceedings, for example the adjacency pair of question/answer in witness testimony, and formulaic language in texts such as the witness's oath. This type of spoken legal language has been, and is still being, extensively studied within a sociolinguistic framework, in which pragmatics has found an important niche. The reader is directed to the articles on legal pragmatics and on definitions and rules in legal language.

At the same time as these developments, another field opened up, a field that has emerged from time to time since Montesquieu and Bentham, but has not until recently attracted the attention of scholars in linguistics and sociolinguistics – the problem of the readability and comprehensibility not only of legal texts but, principally, of spoken legal discourse. The Charrows (1979) conducted a psycholinguistic study of jury instructions, pointing out the low level of

understanding of many jurors, who may have to make fateful decisions concerning matters they do not grasp. Many of the attempts to improve the style of legal documents, to make them comprehensible to the layperson, derive from work on language structure. This research and accompanying public agitation eventually led to the support by U.S. President Carter for plain language in legal documents that directly affect the public, e.g., insurance policies. Many legal firms, especially but not only in the English-speaking world, have adopted plain English in their document writing as company policy (*see* **Jury Instructions**).

The right of silence of the accused, especially in the Anglo–American legal context, has been studied both in terms of its pragmatics, with attempts made to answer the question what the accused means by his or her silence during police investigation, and also in terms of comprehensibility, establishing it as a field of research associated with plain language. Not only has the Miranda warning (in the United States) been under scrutiny as far as comprehensibility is concerned, but in the wake of changes in the text setting out the accused's right of silence carried out in the United Kingdom, linguists have investigated whether the average suspect with a below-average IQ may understand what is being read out to him or her, and what s/he is reading.

Apart from suspects who may not understand what is being said to them by authoritative figures (e.g., police and lawyers), there are other disadvantaged groups who face a linguistic battle in the course of legal proceedings. Litigants and suspects who do not speak, or who have an inadequate knowledge of, the language used in the courts are in many jurisdictions entitled to an interpreter. The various problems arising from interpretation and the rights of the interpreter and the interpreted are discussed in **Court Interpreting**, while other disadvantaged groups, for example aborigines in Australia, which has attracted much research recently, is dealt with in **Interviewing and Examining Vulnerable Witnesses**.

The employment of linguists as expert witnesses in the courtroom has grown over the last two decades or so. The expertise work requested tends to be in the field of voice and writing identification. Much of the research on language in the courtroom is now included in this field of studies. The associated field of intellectual property rights and their violation is an area of current research discussed in **Plagiarism**.

We also find groups of philosophers, linguists, and academic lawyers who examine law and language from a semiotic point of view. The French semiotician Andre Greimas wrote with linguist Eric Landowski a seminal work on legal discourse (1966), followed by further work from a Greimasian perspective by Bernard Jackson (1984). Semiotic research into legal language has also appeared from a Peircian standpoint, and from the Italian analytical school of jurisprudence. A discussion of police/citizen encounters from a semiotic point of view is found in **Legal Semiotics** and **Police Questioning**.

The development of legal language has been studied, especially within the European area. Despite a distinction that needs to be made between common law (Anglo–American) law countries and countries whose legal systems are what is termed continental, developed from the Justinian code to the Napoleonic code and beyond, the language of the law in both systems has much in common. This may be seen, too, in a comparative approach in non-European systems. Furthermore, studies have been carried out on the influence of the law on 'normal' language itself, as may be seen in **Law on Language**.

There remain a number of less prominent areas in which research has been carried out on the law and language. For example, within the model of Roman Jakobson's functions of language, the poetic function of the language of the law has been examined in terms of rhythm, alliteration, parallel structures, and the extensive use of metaphor.

Contributions of the History of English Civilization and Its Influence on Language and Discourses

The exploration of modes of communication in Great Britain permits a better understanding of the mechanisms by which legal order has been integrated into everyday language. The English judicial system has evolved since the 13th century under the influence of the customs of the different ethnic groups that have populated the island. Sir Francis Bacon noted the multicultural aspect of the Laws of England, the contents of which were the result of a compromise between the natural order of things and tribal or clannish values and the desire to homogenize through organized constraints.

The current language system is the result of an organization of meanings and terms from different cultures and traditions imported by invaders. They contributed to the impression and development of oral language and the transmission of orders and knowledge. What is the influence of the various ethnic groups that have contributed to the emergence of the nation?

The Celts, Anglo-Saxons, and Scandinavians participated in the historical construction of the linguistic dialectic between law and language in England. By successive invasions, they transposed their traditions through the development of rules for social life. At that time, customary practices were systematically built because illiteracy was virtually universal: "It is true, indeed, that, in the profound ignorance of letters which formerly overspread the whole western world, all laws were entirely traditional, for this plain reason, that the nations among which they prevailed had but little idea of writing" (Blackstone in Mellinkoff, 1963: 158).

This "plain reason" had fundamental consequences for the creation of an English legal order, which over the centuries came to be based on customs because of the need to articulate the practices and beliefs associated with each ethnic group; the purported objective of such a move was the creation of national unity. Writing was rare, but where it existed, it acquired a supreme value through its solemnity; the Magna Carta of 1215 is a good example, for it established, in English law, the mechanism of the predominantly customary parliamentary system that existed at the time. King Charles I received the ultimate punishment in 1649 for attempting to defy Parliament and trying to modify the Presbyterian religious custom.

The Celts

The influence of the Celts, who practiced human sacrifice and vengeance, bestowed a precise, very complex customary law through their elaborate system of sanctions. The lawyers were artisans of a repetitive oral tradition: "The joint memory of the ancients, the transmission from one ear to another, the chanting of the poets" (Powell, 1985: 159).

Sacred centers (*omphalos*) assured the unity between customs – beliefs and the expression of common language. Notably, the Celts were at the origin of 'legal procedures.' Even if justice was individual, it was rendered by an assembly, meeting as a jury. Resolving conflicts by arbitration resulted in making the law more fluid.

The Justinian Institutes

The Justinian Institutes were the source of judicial language carried by the Romans into the towns they occupied. These were the only hearths of latinization (Walter, 1994: 366) in an environment dominated by the Celtic spirit. The contributions were substantial, as the Latin society imposed the tradition of writing by the intermediary of the clergy, by which the

Contributions of the History of English Civilization and Its Influence on Language and Discourses

The exploration of modes of communication in Great Britain permits a better understanding of the mechanisms by which legal order has been integrated into everyday language. The English judicial system has evolved since the 13th century under the influence of the customs of the different ethnic groups that have populated the island. Sir Francis Bacon noted the multicultural aspect of the Laws of England, the contents of which were the result of a compromise between the natural order of things and tribal or clannish values and the desire to homogenize through organized constraints.

The current language system is the result of an organization of meanings and terms from different cultures and traditions imported by invaders. They contributed to the impression and development of oral language and the transmission of orders and knowledge. What is the influence of the various ethnic groups that have contributed to the emergence of the nation?

The Celts, Anglo-Saxons, and Scandinavians participated in the historical construction of the linguistic dialectic between law and language in England. By successive invasions, they transposed their traditions through the development of rules for social life. At that time, customary practices were systematically built because illiteracy was virtually universal: "It is true, indeed, that, in the profound ignorance of letters which formerly overspread the whole western world, all laws were entirely traditional, for this plain reason, that the nations among which they prevailed had but little idea of writing" (Blackstone in Mellinkoff, 1963: 158).

This "plain reason" had fundamental consequences for the creation of an English legal order, which over the centuries came to be based on customs because of the need to articulate the practices and beliefs associated with each ethnic group; the purported objective of such a move was the creation of national unity. Writing was rare, but where it existed, it acquired a supreme value through its solemnity; the Magna Carta of 1215 is a good example, for it established, in English law, the mechanism of the predominantly customary parliamentary system that existed at the time. King Charles I received the ultimate punishment in 1649 for attempting to defy Parliament and trying to modify the Presbyterian religious custom.

The Celts

The influence of the Celts, who practiced human sacrifice and vengeance, bestowed a precise, very complex customary law through their elaborate system of sanctions. The lawyers were artisans of a repetitive oral tradition: "The joint memory of the ancients, the transmission from one ear to another, the chanting of the poets" (Powell, 1985: 159).

Sacred centers (*omphalos*) assured the unity between customs – beliefs and the expression of common language. Notably, the Celts were at the origin of 'legal procedures.' Even if justice was individual, it was rendered by an assembly, meeting as a jury. Resolving conflicts by arbitration resulted in making the law more fluid.

The Justinian Institutes

The Justinian Institutes were the source of judicial language carried by the Romans into the towns they occupied. These were the only hearths of latinization (Walter, 1994: 366) in an environment dominated by the Celtic spirit. The contributions were substantial, as the Latin society imposed the tradition of writing by the intermediary of the clergy, by which the

imprint of Christianity on the discourse was complete. These written acts made knowledge accessible even with a limited level of literacy. A transformation of the transmission of knowledge and its fixture by written documents can be observed in the numerous royal edicts issued. However, this mutation only concerned an elite. From then on, Latin terms carried both religious and legal meaning. For example, on *Coelesti* and *Inferi*:

> Christianity gave a new meaning to both words. Hell became a place of torment, inhabited by devils, oath-breakers, and other condemned souls. And it was now understood that a good man might live forever in heaven. This shift of emphasis put considerably more wallop into the oath and a deed or will drawn by a literate clergyman who often threatened hell-fire and damnation for those who tried to upset the transfers (Mellinkoff, 1963: 63).

In Latin terminology, for example, the word *cell* (latin: *cella*, Old French: *celle*) meant both a cell in a convent or monastery but would also come to mean a prison.

The Anglo-Saxons

The Anglo-Saxons founded their rules of community life on the principles of family vengeance and redress: *the Wergeld* (compensation). The law of Ethelbert of Kent concerning the social and matrimonial system is an excellent example. The laws enforceable in Kent in effect transposed the Germanic order to protect women, widows, and slaves. On the other hand, they treated murder and theft very harshly (Stenton, 1968 : 97–98).

The legacy of Old English (Mellinkoff, 1963: 46–47), permitting the creation of words by composition, has come down to modern English, and is still used today:

- boc — book, charter, deed
- bocland — land governed by the charter
- folcland — land not governed by the special terms of a charter, but by folk custom
- wer — a man (sometimes also used to mean wergild)
- wergild — man compensation
- wergildpeof — a thief whose criminality had been ended by the payment of his wergild

In modern texts, the terms *hereafter, herein, hereof, herewith* are occasionally found. This historical contribution of Anglo-Saxon adds to the common language by making the terms more precise or even distorting them.

It is one of the first steps towards the creation of a specialized language giving birth to specially adapted expressions. (Gény, 1922, T.3: 460.)

The Normans

The Norman influence reveals the catalyzing effect of written Latin then in use in France. It became one of the principal instruments of diffusion of English law, notably in the elaboration of rules of law and charters. William the Conqueror helped perpetuate the use of Latin because he had understood the limitations of Old English and Old French for expressing Norman judicial ideas (Holdsworth, 1923: 44). Latin was the language *par excellence* of the medieval age (Woodbine, 1943: 411). The concept of Law Latin is described in no uncertain terms: "It is 'barbarous,' 'corrupt,' 'mutilated,' 'dog latin,' and in an Irish version 'bog Latin.' The calmest definition is Webster's: the kind of Low Latin, containing Latinized English and old French words, used in English law" (Mellinkoff, 1963: 73).

William the Conqueror adapted Norman judicial institutions to England, separating the ecclesiastical courts from the secular, but also continuing to use clergymen in judicial posts, thereby perpetuating the use of Latin. He affirmed the compromise in 1086 when he called a grand assembly at Salisbury to: "... cement the union between the indigenous and Norman elements [and to] give the structure an unchallengeable judicial foundation" (Andrieu-Guitrancourt, 1978: 278).

While the English were establishing a power to regulate the life of society, the French were also attempting to unify their judicial practices under French customs. The procedure was the same as that on the other side of the Channel. The '*decretale*' of Innocent III in 1202 addressed to Lothaire, Canon of Paris, posed the problem of Parisian customs (*Coutume de Paris*) directly and incisively. He referred to this custom as a part of the law in France (*quia tamen juxta, consuetudinen approbatam, que pro lege servatur, in partibus gallicanis.*) A great number of other 13th century charters relating to it were issued as law in 1212 by Simon de Montfort to the people of Albigeois and other neighboring regions (charters following the Treaty of Franc-Aleu of 1637).

It is also noticeable that insularity did not drive England to draft original rules parallel to the expression of a multiethnic population. The construction of a derived specialized language is the consequence of a complex maturation of Norman and foreign customs. It results in a common law highlighted by the clergy who integrated Canon law as well as Roman law into it.

The Setting of 'Open Texture'

An 'open texture' (MacCormick, 1978) leads to various possibilities of interpretation within space and time. Indeed, the interpretation of the law is currently made in light of its principal sources, which are statutory law and judicial precedents. The written word is of supreme authority, but is integrated in the English logic of interpretive reasoning. In contrast to countries based on written law where the concept does not allow any transformation, its use in England is flexible. This flexibility is proof that the capacity of the legislative discourse, which is situated – by Act – outside of time and space, can become a living reality. Butler (1997: 25) defines its sense when she affirms that the language "remains alive when it refuses to 'encapsulate' or 'capture' the events and lives it describes." This doctrine is aimed at and authorizes the interpretation of discourse. The two elements that shape the decision are the power of deformation of concepts associated with vague outlines in discourse. Their use by the legislator is not accidental: it is the culmination of a premeditated act whose purpose is to simplify the formulation of written law. Indeterminacy is characteristic of the application of judicial precedents:

> In language the words which present themselves, and are employed in the character of names, are, some of them, names of real entities, others, names of fictitious entities; and to one or other of these classes may all words which are employed in the character of names be referred (Bentham in Tait, 1843: 448–449).

Indeterminacy can also be noticed in the gender, the words, the sense accorded to concepts, and the interpretations in time and space. It reveals the specific identity of its legal and linguistic communities: what is the approach of this interpretation?

Fluidity of Meaning: Cause or Consequence of Judicial Vagueness?

In law, vagueness is understood to be the remnant of doubt in the legal text, outside of the clear meaning flowing from its pronouncement. Plurality in meaning is advantageous since the possibility of more messages implies a larger set to select from.

> But now I employ the expression 'Legal Fiction' to signify any assumption which conceals, or affects to conceal, the fact that a rule of law has undergone alteration, its letter remaining unchanged, its operation being modified... The fact is [...] that the law has been wholly changed; the fiction is that it remains what it always was (Sumner Maine, 1963/1861: 25–26).

This fiction, this voluntary lack of real frontiers between the semiotic logic and the multiplicity of the fields of application leads to instability in discourse between scientific communities. But these 'neighborhood' conflicts are considered beneficial to legal language because of the important role left for interpretation. The English philosopher, John Heron (1989), confronts the sense of this collaboration:

> This construing of what is immediately presented as a spatio-temporal whole that transcends what is immediately presented, is not only a means of experiential knowing, it is also a fundamental kind of practical knowledge – knowing how to orientate oneself in space and time, knowing how to construe presentations or appearance in terms of spatial and temporal 'reality.'

This space for creative liberty is not the result of a misunderstanding or of a lack of completion. It is based on the semantic contents of the text, which by its organization, inserts it into a general body of reflection: the doctrine of indeterminacy. This particular form, for example, places the judge in a relatively open space for decisions; it offers him the possibility to integrate exterior elements into the legal domain within prescriptive arguments. Indeterminacy transforms the partially hermetic reading of the judge who applies the law, in judgments, into a flexible interpretation – *ratio decidendi.*

This doctrine produces social identity but is also a source of cohesion between the individuals of the same scientific community. Bachelier reminds us that "the richness of a scientific concept is measured by its power of deformation" (Grawitz, 1993: 1). This flexibility of concept becomes a living reality, "a kind of **personification** ... as if the law were a living creature" (Bentham in Tait, 1843: 399). The rigid prescriptive frame delimits a content of which the sense varies according to the interpretation of the user.

Theoretical Intepretation The theoretical interpretation of the author's thoughts and his/her productions permits the discernment of several essential elements that condition the tenor of the messages. There is no perfect accord between the thought of the author and his/her production. The deformation operates from the relationship of factual or written elements, which serve to support his/her thoughts. The ambiguity comes out of the personal work and goes on to contribute to the specificity in the identity of the discourse. The elements of shift in meaning are therefore either in the semantic support between constant or variable meaning, or in a time-space that does not correspond to that of the emission of the message. The networking of the listed constraints makes sense and leads to the determination of rigid and fragile elements (i.e., fuzzy sets in the language of the

law that can impair the whole understanding of a sentence). It may be pointed out that writing down the rule is the product of a semantic reflection in which textual organization also takes on sense.

Metacognition The metacognition of the interpreter is important because of the effects of perception of ambiguity integrated in the author's discourse. To that cultural appreciation is added the special knowledge of the reader who has been trained in legal logic. Flavell (1987: 21–30) underlines the effect of doubt, which is present in the cognitive activities that one does not know how to interpret or explain, and in which the construction of knowledge is proportional to the metacognitive implication of the subject.

Application of Ambiguity The application of ambiguity in the judicial act is realized in the form of a readjustment including the user's reasoning through a descriptive process. These contributions are characterized by the emission of procedural rules, drafted in part from law reports conditioned by the rules of precedent. The resulting process provides a compromise between the social parameters introduced and the decision reached. Its aim is to be in a continuum of the legal thought of the time: "Any instance of interpretation always involves a choice and a motive, an element of the 'play of meanings' which denies that there can ever be a single 'correct' or valid interpretation (Goodrich, 1986: 138)."

This handling of meaning and words is the prime feature of the functioning mode of the English legal system. The contribution of specialized linguistics allows the evaluation of the level of logic and fluidity that impregnate the frames of statutory law and precedents, that is of the drafters, readers, and interpreters of the law. This creation of linguistic tools is a challenge to the objectivity of the rules. Some writers mention the limitations made necessary by the fact that realities of social life only become judicial realities thanks to the concepts and decision making capable of providing the necessary meaning. The decision making outside the context of the rule interferes with the legal order but allows the extension of meaning, which can be re-used in other circumstances. This plural reality of linguistics can be noticed in the thinking of Sherry (1996: 134): "The globalization of culture means that we all live in 'translated' worlds that the spaces of knowledge we inhabit assemble ideas and styles of multiple origins, that transnational communications and frequent migrations make every cultural site a crossroads and a meeting place."

Gény (1922: 79–80) completed his notion of fluidity by a more global approach:

> The things of the world submitted to duration are in a constant flux and as the object of a continuous flow in such a way as there is no fixed nature but essences perpetually changing and observing at the same time that the faculties of man do not operate according to a law of schematical dissociation, they operate in a perpetual concert which does not allow to insulate them from one another. The 'new philosophy' energetically criticizes as means of knowledge, the 'discursive process' which leisurely deform reality (like the steps of a stairway which would be substituted to a slow slope), even the pure concepts which only grasp things by fragments and represents them like still and solid moulds incapable of expressing their essential variety and fluidity.

This brief analysis can be summarized by the fact that fluidity is a place of contact, a place of interference, and a mode of cultural production, 'a translated culture' as part of the processes by which newness enters the world (Wagner, 1999).

Indeterminacy in Legal Language

As an illustration, the current language runs on a path of information by means of expression neutral and accessible to everybody. Specialized languages run on the same path but add specialized elements to the current meaning. It, in turn, creates a dynamic of comprehension, a metalanguage only accessible to the initiated. The question is to examine the origin of the specialized term and its semantic transformation.

In the domain specific to legal expression, the linguist works at confronting the conceptual word within the current relationship and the application being construed by the powers that be. He or she then attempts to explain the mechanisms that condition the understanding of meanings both internal and external to the British scientific community. The distortion of meaning of this affected language is particularly perceptible by the other inhabitants of the European continent.

So, the question of reassigning meaning to words and playing with words will continue to be the core issue in legal adjudication, since any word may be subject to interpretation as it was with the case of 'tomatoes' in 1893 (*Nixen v. Hedden*) where the U.S. Supreme Court had to decide whether they were fruit or vegetables. The Court rejected the botanical truth that the tomato is in fact a big berry, and deferred to the culinary vernacular of vegetable to describe it.

As a consequence, statutory wording is not a closed system but an open texture where relative

indeterminacy is used to interpret statutes (Wagner, 2005). "Parliament often uses general words intentionally in the belief that judges are the most adept in filling in the details" (Freeman, 1994: 193).

Indeterminacy will only cease when one momentary experience (i.e., a case in court) is considered. It will then turn into a contextualized determinacy. "Because the meaning of language is inherently contextual, we have declined to deem a statute 'ambiguous', for purposes of lenity merely because it was possible to articulate a construction more narrow than that urged by the Government" (Solan, 2004: 79).

Involuntary Intent of Promoting Ambiguity The language contains several microsystems, which merit examination. Here, the difficulty of interpreting 'and' and 'or' is a well-known phenomenon in law. In a statute, these two terms can be interchangeable from the time that a legislative intention exists (Solan, 1993: 45). Quirk (1986: 934) in the same vein, adds "*or* tends to replace *and* in contexts which we have called non assertive, and more generally in subordinate positions in the sentence." Solan explained that an error in writing by the overuse of the terms 'and' and 'or' allows to invert them. In effect, they are considered by lawyers to be very vague, therefore too general. Their usage as indeterminate notions reflects the legal terminology. In this way, the weak interpretive use of the connector forces the court to take the necessary measures to arrive at the legislative intention. Mellinkoff (1965: 56) said the same thing: "Legal writings continue to spew contradictions joined by a habitual *and/or*."

This controversy is very important to the use of this type of expression. Can it then be considered as an encouragement of mental laziness? Anyone knowing the difference between 'and' and 'or' can take a contract or a law and substitute one or the other term to reach a greater clarification of the law or legal decision.

The term 'and' is used to avoid a construction which, by the use of 'or' only, excludes the combination of several alternatives. 'And' takes the place of an addition, after several connected alternatives, simply by 'any combination thereof.' It takes the place of 'or' and in keeping the same meaning in statutes: 'and any combination thereof' or 'or any combination thereof.' By this, 'and/or' is completely ambiguous. But the courts will accept it without difficulty as a contribution to legal English: "The high failure rate of legal papers that depend on *and/or* for anything of importance should have long since eliminated it from the legal vocabulary. Yet it persists, and is widely used in legal and ordinary writings" (Mellinkoff, 1965: 55).

'Promoted' Indeterminacy Overtly 'promoted' indeterminacy in statutory law was emphasized by U.K. legislators on the use of gender-neutral, gender free language in order to avoid designating grammatical gender and leave doors open to judges' construction. The English Interpretation Act 1978 provides that:

"words importing the masculine gender include the feminine";
"words importing the feminine gender include the masculine," and
"words in the singular include the plural and words in the plural include the singular" (Wagner, 1999).

Even modality has been construed by judges as shown below:

> It is admitted that the words 'every member . . . shall inform' the directors does create an obligation but it is argued by the defendants that the words 'the directors . . . will take the shares' imports in some way the idea of an option or choice or volition on the part of the directors having regard to the inherent difference (not always observed) in the English language between the words 'shall' and 'will.' I appreciate the force of that argument, but I cannot accept it. In this context, while the word 'shall' clearly imports compulsion and obligation, the word 'will' indicates as it seems to me a resultant prospective eventuality, in which the member has to sell his shares and the directors have to buy them, each being under an obligation to bring that eventuality into effect (*Rayfield v Hands* [1958] 2 All ER 194 at 196, per Vaisey J).

> We must endeavour to construe the words, so that "shall and may" [in an agreement for arbitration] may both stand. "Shall and may" will both stand, by our holding them to be imperative. (*Crump v Adney* (1833) 1 Cr & M 355 at 361, per Lord Lyndhurst CB.)

> The words shall and may in general acts of parliament, or in private constitutions, are to be construed imperatively. (*A-G v Lock* (1744) 3 Atk 164 at 166, per Lord Hardwicke LC.)

This deliberate intention to promote indeterminacy is also visible when using adjectives or adverbs that could lead to an interpretive process from the judge. Following the examination of distinctive statutes in various countries, it can be noticed that using such words allows focus on intentional possibilities of interpretation. As an example, under the English Judicial Trustees Act 1896, s.3(1), plurality in interpretation is suggested when the drafters inserted adverbs such as 'reasonably' or 'honestly,' which

convey an emotional content. Indeed, both adverbs are vectors of perception of the universe, and from one case to another interpretation can easily fluctuate. Another example is to be found under the proviso of the Australian Criminal Law Amendment Act 1922, s.2, where it is provided that there is a "reasonable cause to believe that a girl is of or above the age of 16 years." How do we determine this reasonable cause? Only a specific case can give an answer to the question.

The Canadian Landlord and Tenant (Rent Control) Act 1949, s.3 (1) (b) deals with the 'reasonable price' to be charged. Here, the evaluation of 'reasonable price' is highly dependent on the context. In other words, indeterminacy is a medium of communication permitting the nondetermination of the constituent words. Words lack effective referents. They are idle, they are not connected with a 'living reality' but with statutes, and their determination will be provided only when exemplified.

Even the simplest words ('person' and 'night' in this case) can have an abundance of meanings in the light of distinctive Acts, for example:

- In the Statute of Frauds Amendment Act 1828, it is provided that 'person' includes a 'corporation.'
- Under the Interpretation Act 1978, Sch.1, 'person' includes a body of persons corporate or unincorporated.
- In the light of Railway Clauses Consolidation Act 1845 (c.20), s.20 'person' includes a limited company.
- What time shall be considered 'night': provided always that for the purposes of this Act the night shall be considered and is hereby declared to commence at the expiration of the first hour of sunset and to conclude at the beginning of the last hour before sunrise (Night Poaching Act 1828, s.12)
- 'Night' "Means the time between half an hour after sunset and half an hour before sunrise" (Highways Act 1980, s.329(1)).

Hypercodification of Legal Language

Hypercodification is one of the characteristics of modern societies, which want to embrace the multiple facets of social life by speech or writing. One of the defining features of modern societies is their embrace of plural writing and speaking systems, a trend that is mirrored in the diversity of social life in general. It is a quest of meaning, the modalities of which seem to pervert the spirit. The exploration of this state of facts does not limit itself to its legal signification but circles the subject in its linguistic expression. This overabundance of modeling systems disturbs the conditions of emission, reception, and meaning of the messages.

The semiotic approach is one of the unavoidable modalities where investigating is carried out by the analysis of the practices of the legal community, notably in its system of values and behavior.

The hypercodification, which is very important in English Law, is part of the message. It can be understood as a means, a mode of expression showing that the legal culture is being communicated. The understanding of the phenomenon results from the exceptional conditioning of the discourse by historical heritage, the multiform contributions being the result of the mixing of cultures and customs of a multiethnic nation. Besides, the external interference has led to the amplification of legal productions and processes. Culler (1981) describes the mechanisms, which have resulted in the inflation of the legal system by the internal interrelations between written and symbolic languages.

Linguistic Territory

The linguistic territory has, in its organization, multiple forms of actions on law by the effects of symbolization, codification, normalization, and even standardization of the language. All of the operations undertaken are intended to simplify the structure of writing and make it more comprehensible. The main idea is to limit the length as well as the complexity of phrases. To achieve this simplification, several techniques have been elaborated. The stated goal is to put into practice a codification that is relatively stable, simple to understand and capable of being added to. In effect, the realization puts in place the means which, under the pretext of simplification, contribute to the complication of the original sense of the text.

Legal Identity

Legal identity is under constant reconstruction. In reality, this reconstruction is a legal one, which adds to the already existing foundation. This new formulation leads to modifications in the discourse by means of textual contributions, which create more inconveniences than advantages. The encoding entails an overabundance of codification. Its interpretations become more and more complex over time. They create an insidious rigidity of legal language. The consistency of discourse is dependent upon its comprehension; so as it is meant first of all for initiates, people outside of the community cannot understand it. The heritage of the Common Law is rich in concepts, in particular meanings, which hold true

only for England and Wales. To show how the law has become a medium, a vehicle, in the same way as the common language, of a highly codified and specialized language, it is necessary to explore its terminological construction. This necessity results from structured collective procedures by systems of abbreviation and terms of variable content. Hypercodification is so highly visible in legal language and the understanding of legal language varies within space and time.

A Tool of Socialization

The language of the law as a tool of socialization and factor of identity generates subproductions, which add new rules by its willingness to adapt in time and space to the English population.

The conveyed message traps legal language by the implication of networks and persons in which specific codes are structured in socio-autonomous systems. One example among others is in English medical law (The Human Fertilisation and Embryology Act 1990), in the case of surrogate mothers, where the adoptive mother is called the 'genetic mother.' In society, the mother who delivers the child is by definition the genetic mother.

Conclusion

Law is, by definition, the codification of modes of expression in a given society. However, its use is distinctive owing to the circumstances in space and time in which users apply or modify it. The shift in meaning between the product and its expression has been analyzed showing how the language of the law can be multifaceted.

Le Roux, Pierre (1874–1975)

P-Y Lambert

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 4, pp. 2061–2062 © 1994, Elsevier Ltd.

Born in 1874 in Plouëc (Côtes du Nord), Pierre Le Roux was a native speaker of the Breton language. He went to the University of Rennes, where he had Joseph Loth (*see* **Loth, Joseph (1847–1934)**) and Georges Dottin as his professors. His first work was a phonetic description of consonant mutations in his own dialect (Pleubian), a study published in 1896. With the help of a scholarship (Fondation Thiers), he came to Paris in 1898, and attended the lectures of the Celticists Gaidoz and D'Arbois de Jubainville. He succeeded Joseph Loth as teacher of Celtic in Rennes University in 1910.

For his thesis, he wrote a historical description of the Breton verb (1930), which qualified him as Professor. This book is an invaluable description of all the paradigms of the verb, from a historical and comparative point of view. It has never been replaced either in respect to the extensiveness of its sources or the accuracy of his analyses. For many of his interpretations (and particularly for the description of the verbs meaning 'to be'), Pierre Le Roux was inspired by two great precursors: Emile Ernault and François Vallée.

At the university, Pierre Le Roux started his dialectological investigations (1911–1913, resumed after the war in 1920–1921). He used to travel on his bicycle across Brittany, sometimes with cumbersome recording instruments. His results were published as a Linguistic Atlas of the Breton-speaking part of Brittany (the first fascicle was published in 1924, the 6th in 1963 with the help of Canon Falc'hun (*see* **Falc'hun, Francois (1909–1991)**). The questionnaire included more than 1200 questions, but only 680 maps have been published. He prepared the questionnaire in Rennes with the help of young Breton-speaking soldiers from different parts of Brittany. He had to limit himself to 78 places of inquiry, a rather loose network compared with the number of Breton-speaking communities (600 parishes).

This Linguistic Atlas recorded forms from dialects that are now extinct, for example, those of Bourg-de-Batz, Belle-Ile, and some places east of Vannes. The informant was chosen very carefully, with an investigation of the birthplace of parents and spouse. In some cases, however, Pierre Le Roux was obliged to rely on the hasty answers of people he was necessarily in touch with: tenants of inns and public houses. All in all, the documents gathered by Pierre Le Roux are an extraordinary witness to the Breton language spoken during the period. Even in the places where Breton is still spoken, it is certainly impoverished in its phonetics, lexicon, morphology, and syntax. The Linguistic Atlas inspired several new investigations into Breton dialectology and phonetics, particularly by François Falc'hun, who studied on this basis the linguistic geography of Brittany, and by Pierre Trépos, whose thesis on the morphology of the plural relied also on the data of the Linguistic Atlas.

Soon after becoming Dean of the Faculty of Arts at Rennes in 1944, Pierre Le Roux retired and lived quietly for the rest of his life; he died a centenarian in 1975. Among his publications were also some editions of older manuscripts (Breton songs of the Penguern collection).

Learners' Dictionaries

M Rundell, Lexicography MasterClass, Canterbury, UK

© 2006 Elsevier Ltd. All rights reserved.

The monolingual learners' dictionary (MLD) – a type of dictionary designed specifically to meet the needs of non-native language learners – is above all an English phenomenon or, even more specifically, a British one. This is not to deny that there have been significant contributions in other languages and traditions. For example, Larousse's *Dictionnaire du français langue étrangère* (1987) was an interesting and in many ways innovative addition to the MLD canon. But it failed to establish a durable parallel thread to complement developments in English pedagogical lexicography. More recently, new learners' dictionaries have appeared for a number of European languages, including: Langenscheidt's *Großwörterbuch Deutsch als Fremdsprache* (1993), the Vox *Diccionario para la Enseñanza de la Lengua Española* (1997), Van Dale's *Pocketwoordenboek nederlands als tweede taal* (2003), and Nathan's *Dictionnaire de didactique du français langue étrangère et seconde* (2003). To a significant degree, however, these have tended to adopt the main features of the dominant British model. In the Anglophone world, meanwhile, several American publishers have entered the fray – with books such as *The American Heritage English as a Second Language Dictionary* (Houghton Mifflin, 1998) and *Random House Webster's dictionary of American English* (1997) – but their efforts have for the most part been highly conservative and have contributed little of interest to the field. On the theoretical front, our understanding of the lexicon has been greatly advanced by work in French, notably in the elaboration of lexicon grammars by Maurice Gross and his colleagues (*see* **Lexicon Grammars**). Nevertheless, the most powerful impetus in the development of MLDs has been – and remains – the practical challenge of providing language learners with the resources to meet their twin communicative needs: 'receptive' understanding and 'productive' use of a second language.

The foundations of the MLD were laid down in the 1920s and 1930s by a handful of British academics, including Harold Palmer, Michael West, and A. S. Hornby, whose theoretical interests in syntax, phraseology, and what would later be called collocation were motivated above all by their work in English language teaching. The story of the modern English learners' dictionary begins in 1935, with the publication of West's *New Method English Dictionary* (*NMED*), a fairly slim volume covering around 18 000 headwords. But it was Hornby's larger *Idiomatic and Syntactic English dictionary* of 1942 that was to prove the more enduring model – evolving as it did into the *Oxford Advanced Learner's Dictionary* (*OALD*, now in its seventh edition), which formed the template for most subsequent, major English dictionaries for advanced learners. Over 60 years on – despite a highly competitive market that has delivered an impressive series of innovations – Hornby's blueprint survives substantially intact. Numerous publishers have entered the field (and with over a billion people learning English worldwide, this is hardly surprising), and have experimented with a wide range of general and specialized learners' dictionaries for all levels of proficiency. The advanced-level MLD, however, remains the dominant format. Since the 1970s, Hornby's dictionary has been joined by several other U.K.-based contenders: the *Longman Dictionary of Contemporary English* (*LDOCE*, 1978), the *Collins COBUILD English Language Dictionary* (*COBUILD*, 1987), the *Cambridge International Dictionary of English* (*CIDE*, 1995), and the *Macmillan English Dictionary for Advanced Learners* (*MED*, 2002). Yet amid all this diversification, the trend is toward ever closer convergence in both form and content. Quite major upheavals (notably the publication by Collins of the first *COBUILD* dictionary in 1987) have been assimilated into an increasingly homogeneous model, as last year's innovation becomes this year's standard feature. Though experts will perceive numerous differences among the main players, what the average user sees is a set of very similar dictionaries that share a great many core features. To give a single (and fairly superficial) example of this convergent trend, the fourth edition of the large *COBUILD* dictionary (2003) has added the term 'advanced learner's dictionary' to its title (along with the MLDs produced by Oxford and Cambridge), has shrunk its (originally larger) format to 'standard MLD' size, and has, for the first time, included illustrations – thus bringing itself more closely into line with the other main dictionaries of this type.

Main Features of the MLD: A Summary

The features that have become a standard part of the MLD are summarized here, and the most important of these will be elaborated in the next section.

In terms of the dictionary's receptive function (helping users understand vocabulary items they have encountered):

- definitions are written in simple language, typically using a controlled 'defining vocabulary' of basic words;
- phraseology gets special attention: the MLD generally goes further than other types of dictionary in explaining the meanings not only of individual words but also of multiword expressions of every type;
- aids to navigation are provided (in the form of reduced definitions, appearing as 'signposts' or in menus) in order to minimize the known problems involved in locating the 'right' information.

In terms of the dictionary's productive function (helping users to make appropriate lexical choices and then use the chosen item 'correctly' and idiomatically):

- syntactic information provides users with a full account of the valence patterns that a given word or meaning enters into;
- example sentences are used extensively to show typical contexts of use and provide reliable models for production;
- considerable attention is paid to sociolinguistic features such as register, regional variety, and speaker attitude;
- usage notes provide supplementary guidance, e.g., facilitating lexical choices by disambiguating sets of close synonyms or warning against known sources of grammatical error.

In More Detail

Definitions

Here, three features distinguish the MLD from other dictionaries:

1. The use of a controlled 'defining vocabulary' (DV), enabling (perhaps a better word would be 'forcing') lexicographers to explain meanings through a limited list of basic, high-frequency words. From the beginning, a simplified defining language was one of the central features of the learners' dictionary. Three of the early pioneers in this field, Harold Palmer, A. S. Hornby, and Michael West, had a special interest in the notion of 'vocabulary control,' which arose – as Cowie (1999: 15) points out – "from a simple pedagogical need: to reduce the effort required to learn a foreign language by identifying those (relatively few) words which carried the main burden of communication." The process became more formalized when Longman – drawing on West (1953) – introduced a 2000-word DV in the first edition of the *Longman Dictionary of Contemporary English* (*LDOCE*) (1978). This approach was gradually emulated, so that at the time of writing four of the five major advanced MLDs employ a DV limited to 2000–3000 common words.
2. A preference for natural language: the past 15 years or so have seen a marked shift away from the formal, compressed, and often idiomatic language of traditional lexicography, toward a user-friendly style that conforms more closely to 'normal' prose (see esp. Rundell, 1998: 332–334). The following comparisons make the point:

NMED, 1935	**pain:** suffering of body or mind
*OALD*6, 2000	**pain: 1.** the feelings that you have in your body when you have been hurt or when you are ill **2.** mental or emotional suffering
*OALD*3, 1974	**aggressive:** quarrelsome; disposed to attack
*LDOCE*4, 2003	**aggressive:** behaving in an angry or threatening way, as if you want to attack someone

3. 'Full-sentence' defining: one of the major innovations in *COBUILD* (1987) was to abandon the 'substitutable' definition of traditional lexicography in favor of a defining sentence which includes the headword itself in its typical lexico-syntactic context. (The genesis and rationale of this approach is explained in Hanks, 1987, and discussed further in Sinclair, 2004.) To illustrate the difference this can make, a conventional definition might explain the phrasal verb *lay up* as 'to cause sb to stay in bed, not be able to work etc.' (*OALD*4, 1989). But in the *COBUILD* version ('If someone is **laid up** with an illness, the illness makes it necessary for them to stay in bed': *COBUILD*4, 2003), the structure of the definition matches the passive form in which this verb usually appears, while the prepositional phrase that typically accompanies it is fully integrated into the explanation. Though the *COBUILD* dictionaries are unique in employing this defining style in all cases, the full-sentence definition has an established place in the repertoire of definition types available to compilers in most of the English MLDs.

Syntax

Since Harold Palmer introduced his system of 'verb patterns' in 1938, descriptions of syntactic behavior have been a core feature of the MLD. Earlier MLDs were characterized by the use of elaborate coding schemas which, though descriptively powerful, were difficult to learn and mutually incompatible. Palmer's system was taken up and refined in *OALD*, while

LDOCE (1978) introduced an entirely different (but equally complex) approach based on alphanumeric codes. More recently, the emphasis has shifted toward a simpler, surface-grammar model which – while sacrificing some of the delicacy of earlier systems – assumes very little grammatical knowledge on the part of users. Compare the following accounts of the syntactic properties of the verb *recall*:

*OALD*3, 1974	[VP6A, C, 8,9,10, 19C] bring back to the mind; recollect: *I don't recall his name/face/meeting him/where I met him.*
LDOCE, 1978	[Wv6; T1,4,5,6a,b] to remember: *I can't recall his face/seeing him/that he came/where he lives/how to do it.*
MED, 2002	[I/T] to remember something: *Twenty years later, he could still recall the event.* ♦ +(**that**) *I seem to recall that you said you would do that yesterday.* ♦ +**who/where/why etc.** *Stephen frowned, trying to recall what had happened.* ♦ **recall doing sth** *I don't recall seeing the document.*

The economy of the older systems allows them to encode every *possible* pattern for a given meaning, regardless of its frequency: thus, the *OALD*3 code VP19C indicates the construction V+noun/pronoun/possessive+gerund (*I don't recall you saying that*), but – tellingly – the pattern is not exemplified. And in fact, corpus data shows it to be extremely rare, with just five occurrences in the 5500 or so instances of the verb *recall* on the British National Corpus (BNC). (Conversely, the simple V+gerund pattern – encoded as VP6C in *OALD*3 – appears over 150 times in the BNC.) The current approach – exemplified here by *MED* but equally likely to be found in other MLDs – emphasizes what is typical over what is possible, and uses corpus-derived examples to complement the user-friendly patterning information. And as with most other features of these dictionaries, there is now a fairly high degree of convergence among the various MLDs in their approach to describing syntax.

Examples

Dictionaries for native speakers (especially historical dictionaries) have generally used citations for purposes of illustration and attestation. By contrast, the examples in learners' dictionaries have always had a consciously pedagogical function. In the earlier MLDs, there was little emphasis on replicating actual performance: rather, examples tended toward the formulaic, often taking the form of short noun phrases or infinitive statements ('*inordinate desire*,' '*a football fixture*,' '*to instil knowledge*': all *NMED*, 1935), or merging several patterns into a single 'sentence' (see examples above, under 'Syntax'). The current range of MLDs, however, favor fuller and more natural examples taken from a corpus (or at least closely reflecting what the corpus shows). For a while (following the publication of *COBUILD* in 1987 and the advent of corpus data), there appeared to be a philosophical split between those who used 'made-up' examples and those who advocated the use of unmodified corpus lines (see e.g., Laufer, 1992; Potter, 1998). This debate had some mileage at a time when the use and availability of corpora was still limited, but it is no longer really relevant. (It also, very misleadingly, encouraged the perception that the main value of a corpus was as a source of dictionary examples.) Now that all serious MLDs use corpus data as their primary source of linguistic evidence, methodological differences among the various editorial units, in terms of how examples are chosen for the dictionary, have become fairly minimal.

The Impact of Corpora

Learners' dictionaries have introduced many innovations which have subsequently influenced other areas of lexicography. By far the most important of these, it goes without saying, is the systematic use of corpus data as the primary basis of dictionary text. Pioneered by John Sinclair and his colleagues in Birmingham, corpus lexicography burst upon the world in the form of the first *COBUILD* dictionary (1987), and the methodology was quickly taken up by other dictionary developers of all types. For those working at the coal face, the change in working practices has been almost total. As far as dictionary content goes, improvements in quality (above all in the area of semantic analysis) have been very significant. Corpus data has also enabled lexicographers to provide categories of information which were simply not available before. Notable examples are the explicit indicators of word frequency which now appear in most advanced MLDs (see e.g., Kilgarriff, 1997), and the lists of typical collocates shown first in *MED* (2002) and already becoming a standard feature (Kilgarriff and Rundell, 2002). These are enormous changes by any standards, and the longer-term impact of the corpus revolution (in terms of its challenges to existing linguistic assumptions and categories) is still far from clear. Yet despite all this, the MLD remains recognizably the same object as it was before the arrival of corpora.

Signs of Change

We are now, however, seeing signs that this durable paradigm is beginning to break down. New technology – supplying vastly improved linguistic data, and at the same opening up new media for delivering reference materials to users – has created conditions which threaten the well-established MLD model but at the same time present extraordinary opportunities for producing better dictionaries and for customizing them to more effectively meet the needs of users.

The advanced MLD has always been a global product: a general-purpose dictionary intended for learners from widely different linguistic and cultural backgrounds. It now seems unlikely that this format will survive indefinitely. Already we see some erosion of this position with the publication of country-specific editions, which offer anything from minor levels of customization – such as a Chinese or Japanese introduction with user guides in the 'local' language – to full-scale 'bilingualization,' with L1 equivalents supplied for each sense and translations of the example sentences. This trend looks set to intensify, given the possibilities offered by electronic media, and the global MLD might in future become just one among many types of learners' dictionary.

For most of its lifetime, the MLD appeared only in the form of a printed book, but learners' dictionaries are now routinely available on CD-ROM and handheld devices, and many also have an online presence. This is a rapidly changing scenario, and exactly how it will play out is anybody's guess. There will probably always be a demand – in some parts of the world at least – for printed dictionaries, but it is safe to assume that some form of electronic platform will become the primary delivery medium for the MLD in its most important markets. The possibilities here are only just beginning to be exploited. Most electronic dictionaries have replicated the content and structure of their printed originals, simply adding friendly interfaces and increasingly smart search functionality. But the next generation is now emerging – a good example being the CD-ROM version of *LDOCE*4 (2003), which gives users access to a 'hinterland' of additional examples and corpus citations for almost every word and phrase. Links between dictionary and corpus are just one of the possible ways in which the MLD will develop from here, and we may look back on the first decade of the new millennium as the point at which the one-size-fits-all MLD began to diversify into a range of more specialized reference resources.

Learning Sign Language as a Second Language

Sign languages are natural languages. This means that sign languages are often learned as second languages, just like spoken languages. Unlike spoken languages, however, sign languages are expressed with the hands, arms, and face and understood through the eyes. This means there are two kinds of second sign language learning: unimodal second language learning, where a person knows two or more sign languages, and bimodal second language learning, where a person knows one or more sign languages and one or more spoken languages. An important question, then, is whether the sensory-modality of the first and second languages changes what we know about second language learning over the life span. Another important question is whether and how the age of first language learning affects the ultimate outcome of second language learning. Clearly several factors in the second language must be considered in any account of second language learning of sign languages, sensorimotor modality, the temporal order of the first and second language learning, and the ages when the first and second languages are learned. Here we focus first on second language (L2) learning when the first language (L1) learning begins in early childhood. We consider both simultaneous and sequential L1 and L2 learning. Next we consider L2 learning in the case where L1 learning begins after early childhood.

Learning Two Languages in Infancy

Babies whose parents use a sign language with them in infancy often learn two languages simultaneously. One kind of L2 learning is by hearing babies whose deaf parents use a sign language with them. They typically acquire both a sign language and a spoken language. This is an example of bimodal bilingualism. The ages when these babies reach their early language milestones – such as the appearance of the first word, the first 50 words, and the first word combinations – are similar to those of babies learning two spoken languages and babies learning only one language, signed or spoken (Petitto *et al.*, 2001). The early vocabularies of babies acquiring both a signed and a spoken language are semantically similar across the two languages, although the specific vocabulary items are not identical. Fewer than a third of the vocabulary items the child knows in each language are translation equivalents, similar to children acquiring two spoken languages. The vocabulary sizes of babies learning a signed and a spoken language simultaneously are similar to those of babies learning only one spoken language, especially when the lexical items of the two languages are considered together, as is the case for babies learning two spoken languages (Holowka *et al.*, 2002; Pearson *et al.*, 1993).

Babies who are deaf and whose parents use a sign language with them from birth often learn an L2 at the same time. The L2 may be another sign language, but unfortunately little is known about bilingualism in the visual modality. More is known about bimodal bilingualism. For example, when learning both SLN (Sign Language of the Netherlands) and Dutch, one deaf baby was observed to begin learning vocabulary in SLN. The child then used the sign vocabulary to help learn Dutch vocabulary items up to 36 months. In an intermediate stage, the child both signed and spoke vocabulary items. The child eventually separated the vocabularies of the two languages and either expressed signs without speaking or spoke words without signing. Around the same age, the child showed an awareness that the word order patterns of SLN and Dutch are not the same (Hoiting, 1998).

Learning Two Languages Sequentially

Adults and adolescents frequently learn sign languages as second languages. Hearing adults may learn sign languages for professional reasons. Teachers, interpreters, therapists, and researchers working with

Sign languages are natural languages. This means that sign languages are often learned as second languages, just like spoken languages. Unlike spoken languages, however, sign languages are expressed with the hands, arms, and face and understood through the eyes. This means there are two kinds of second sign language learning: unimodal second language learning, where a person knows two or more sign languages, and bimodal second language learning, where a person knows one or more sign languages and one or more spoken languages. An important question, then, is whether the sensory-modality of the first and second languages changes what we know about second language learning over the life span. Another important question is whether and how the age of first language learning affects the ultimate outcome of second language learning. Clearly several factors in the second language must be considered in any account of second language learning of sign languages, sensorimotor modality, the temporal order of the first and second language learning, and the ages when the first and second languages are learned. Here we focus first on second language (L2) learning when the first language (L1) learning begins in early childhood. We consider both simultaneous and sequential L1 and L2 learning. Next we consider L2 learning in the case where L1 learning begins after early childhood.

Learning Two Languages in Infancy

Babies whose parents use a sign language with them in infancy often learn two languages simultaneously. One kind of L2 learning is by hearing babies whose deaf parents use a sign language with them. They typically acquire both a sign language and a spoken language. This is an example of bimodal bilingualism. The ages when these babies reach their early language milestones – such as the appearance of the first word, the first 50 words, and the first word combinations – are similar to those of babies learning two spoken languages and babies learning only one language, signed or spoken (Petitto *et al.*, 2001). The early vocabularies of babies acquiring both a signed and a spoken language are semantically similar across the two languages, although the specific vocabulary items are not identical. Fewer than a third of the vocabulary items the child knows in each language are translation equivalents, similar to children acquiring two spoken languages. The vocabulary sizes of babies learning a signed and a spoken language simultaneously are similar to those of babies learning only one spoken language, especially when the lexical items of the two languages are considered together, as is the case for babies learning two spoken languages (Holowka *et al.*, 2002; Pearson *et al.*, 1993).

Babies who are deaf and whose parents use a sign language with them from birth often learn an L2 at the same time. The L2 may be another sign language, but unfortunately little is known about bilingualism in the visual modality. More is known about bimodal bilingualism. For example, when learning both SLN (Sign Language of the Netherlands) and Dutch, one deaf baby was observed to begin learning vocabulary in SLN. The child then used the sign vocabulary to help learn Dutch vocabulary items up to 36 months. In an intermediate stage, the child both signed and spoke vocabulary items. The child eventually separated the vocabularies of the two languages and either expressed signs without speaking or spoke words without signing. Around the same age, the child showed an awareness that the word order patterns of SLN and Dutch are not the same (Hoiting, 1998).

Learning Two Languages Sequentially

Adults and adolescents frequently learn sign languages as second languages. Hearing adults may learn sign languages for professional reasons. Teachers, interpreters, therapists, and researchers working with

children and adults who are deaf often learn sign language in university courses designed for them. The first stage of adult L2 learning of sign languages is characterized by a marked reliance on the perceived iconic features of signs. Beginning signers use iconicity as a mnemonic aid to remember new vocabulary items for both sign expression and recognition (Campbell *et al.*, 1992). Beginning sign learners often want to know the mimetic 'reason' for every sign form. Although sign languages are rooted in manual gesture, they are not iconic by nature. To the contrary, all sign languages have phonological structure, that is, meaningless articulatory units that combine to make the words of the language. Research shows that signers manipulate the phonological structure of sign languages during language comprehension and expression, just as phonological structure is a basic part of listening to and speaking a spoken language.

A key difference between adult L2 learning and infant learning of sign languages is that iconicity plays no role in infants' vocabulary learning. Moreover, iconicity plays no role in the human mind's comprehension of sign language for both L2 and L1 signers who are highly proficient. Beginning signers may recruit what they already know that is close in nature to sign language, namely in gesture and pantomime. This may help beginning signers learn how to position their fingers, hands, and arms in making signs and serve as a means to remember the meanings of the signs they are seeing for the first time. The strategy may be analogous to beginning speakers of a second language using the sound patterns of their native language to help themselves remember the sound patterns of a new spoken L2 they are learning. Clearly L2 learners abandon this strategy once they learn the phonological structure of the sign language.

Beyond vocabulary learning, L2 learners of sign languages must also master morphology and syntax. One problem for L2 learners is that the syntax and morphology of natural sign languages are not always taught in sign language courses. Many courses primarily teach the frozen lexicon of sign languages, excluding classifier constructions, along with finger spelling. This teaching method inadvertently encourages beginning L2 learners to express sign language vocabulary using the word order patterns of their spoken L1. The result is a kind of pidgin where L2 content words (vocabulary for people, actions, internal states, and objects) are signed according to the word order of the L1 and devoid of the morphology and syntax of any language.

Adults and adolescents who are deaf and who acquired an L1 in early childhood often learn sign languages as second languages. For example, L1 learners of a sign language may later learn some other sign language as an L2, an example of bilingualism in the visual modality. This is common where sign languages are in close geographical proximity, as is the case for LSQ (Langue des signes québeçoise) and ASL (American Sign Language) in Canada. Another possible example of bilingualism in the visual modality is the L2 sign language learning by deaf adults and adolescents who are proficient in a spoken L1, which is often in a read and lip-read form. These L2 learners are more likely to immerse themselves in Deaf communities than hearing L2 learners of sign languages and for this reason are more likely to achieve higher levels of ultimate proficiency than their hearing L2 peers.

Another type of sequential L2 learning of sign languages is found in educational projects that teach BSL (British Sign Language) or ASL (American Sign Language) to kindergarten and elementary school children as a second language (Daniels, 2003). Other programs teach sign languages to hearing elementary school children to enhance their reading and spatial cognitive skills. Yet other programs use signs with hearing children who are delayed in their spoken language development, such as children with autism or Down syndrome. The sign learning in the latter instances is more properly considered L1 rather than L2 learning, however.

Delayed L1 Learning and L2 Learning

The common definition of L2 learning is the learning of a second language simultaneously with, or subsequent to, learning a first language. Although L1 learning in early childhood is the norm for babies born with normal hearing, because they are immersed in spoken language, it is not the norm for babies born deaf. A minority learn sign language from birth because their parents use a sign language with them, as discussed earlier in this article. However, the majority of babies born deaf are isolated not only from the languages spoken around them but also from sign languages if their parents do not sign with them. Even after the initial diagnosis of hearing loss and onset of intervention services for the deaf child, sign languages are often withheld from them in the belief that doing so encourages deaf babies to learn to speak. Note that this is contrary to the popular trend in North America of teaching signs to hearing toddlers because it reduces frustration for the parent and child (Goodwyn *et al.*, 2000), and to the clinical case reports of deaf babies making faster progress learning spoken words after they have learned a sign lexicon. The important point to remember is that sign language learning for many deaf children and

adolescents is not L2 learning but is in reality L1 learning begun at an abnormally late age, i.e., after early childhood.

Learning an L1 for the first time after early childhood has a plethora of negative effects on adult language comprehension. For example, the ability to comprehend and remember sign language sentences and stories declines as the age of L1 sign language learning increases. This is apparent in the kinds of lexical mistakes that delayed L1 learners make when engaged in sign language comprehension and production tasks. They often make phonological errors, producing lexical items that are real signs but with forms that violate the semantic and syntactic framework of the sentence they are reproducing (see **Figure 1**). By contrast, L1 learners who learned sign language from birth, or shortly thereafter, make few lexical errors, and the ones they do make maintain the syntactic and semantic frame of the sentence they are reproducing. Delayed L1 learners also show a reduced ability to comprehend sign language.

The effects of delayed L1 learning are also apparent on grammatical knowledge of sign language. For example, delayed L1 learners are more likely to delete grammatical inflections from signs when producing sign language sentences, whereas early L1 learners either inflect signs or express the same meanings in separate lexical units. Highly delayed L1 learners have been observed to perform at near chance levels on grammatical tasks in sign language.

Figure 1 Panel A shows the sign AND in the ASL sentence 'I ate too much turkey AND potato,' which was the target sentence. Panel B shows the phonologically based substitution error, which resulted in the sentence 'I ate too much turkey SLEEP potato.' Note that the target and error differ in only one phonological parameter: place of articulation. (From Mayberry R 1996. 'The importance of childhood to language acquisition.' In Goodman J C & Nusbaum J C (eds.) *The development of speech perception*, p. 68. Cambridge: MIT Press. Illustration by Betty Raskin © R. Mayberry, with permission.)

By contrast, early L1 learners of sign languages tend to be grammatically accurate.

Delayed L1 learning not only affects the ultimate proficiency with which the L1 can be understood and expressed but also affects the ultimate outcome of L2 learning crossmodally. Early L1 learners of sign languages often show near-native levels of L2 proficiency. For example, people who were born deaf and acquired a sign language early in life often show high levels of L2 learning of spoken languages in read and lip-read forms. By contrast, people who were born deaf and did not experience a fully perceptible language until after early childhood, i.e., delayed L1 learners, typically show low levels of L2 spoken language proficiency in read and lip-read forms. In other words, there is a strong relationship between the age when the L1 is learned and the L2 outcome, independent of the sensorimotor modalities of the languages. Although the linguistic, cognitive, or neural reasons that early L1 learning is necessary for L2 learning to be successful are not understood at present, it is clear that any discussion of L2 learning of sign languages requires consideration of the age when the L1 learning begins.

We return now to the two questions posed at the beginning of this article. First, does the sensorimotor modality of the first and second languages change what we know about how second languages are learned over the life span? The second question is how the age of first language learning affects the ultimate outcome of second language learning. Much of what we know about second language learning of sign languages suggests that there are few differences between second language learning of sign languages and of spoken languages, as has been previously found for infant L1 learning of sign languages compared with spoken languages. One exception appears to be the initial iconic strategy that adult second language learners of sign languages use to begin to parse and remember the phonological forms of signs. The second crucial difference is the age when individuals born deaf first experience a fully perceptible language. It appears that the timing of first language learning during the life span sets the course for all subsequent language learning regardless of the sensorimotor modality of the language learning.

Recorded history in Lebanon goes back almost 5000 years to the times of the Phoenician seafaring traders. Arabic was introduced into Lebanon with the Arab conquest in 634–636 A.D. Since the Middle Ages, Lebanon has acquired a reputation for comparatively tolerant politics and has become home to a number of smaller religious and ethnic groups of the area.

After the end of the Ottoman Empire, Lebanon was under French mandate from 1920 until it gained independence in 1943. From 1975 until 1991, the country suffered from a civil war, which also involved the neighboring countries, Israel and Syria, and the Palestinian Liberation Organization. Since the end of the civil war, the political system has addressed the representation of the interests of different ethnic and religious groups – including Sunni and Shia Muslims, Druze, and various Christian sects – in the country.

The official language of Lebanon is Arabic, which is also the native language of the large majority of its 3.7 million inhabitants. As in other countries of the Arab world, there are two types of Arabic in Lebanon in a diglossic relation: Modern Standard Arabic, which is used in formal contexts, in the media, and in writing, and Levantine Arabic (South Levantine Spoken Arabic) dialects, which are used for spoken and everyday communication. The adult literacy rate in 1990 was 80.3%.

In addition to Arabic, about 234 600 Lebanese (or 6% of the population) speak Armenian, for which an active printing and publishing industry exists. Aramaic (Assyrian and Chaldean Neo-Aramaic) is only used as a religious language in Lebanon, although it is still found as a spoken language in neighboring Syria.

Because of Lebanon's long tradition as a center for international trading and commerce, French and, more recently, English enjoy a high status in Lebanon and are comparatively widely known. Contact with foreign languages is reinforced through large Lebanese communities living abroad, especially in France, the United States, and South America.

"*Cognito verborum prior est, cognito rerum postior est*," said Erasmus. If the knowledge of law is more 'potent,' the knowledge of language is 'prior.' Language undoubtedly plays an important role in the construction, interpretation, negotiation, and implementation of legal justice. It is through a variety of legal genres that an attempt is made to create and maintain a model world of rights and obligations, permissions and prohibitions. In principle, this model world is designed to be consistent with the vision that individual states or nations have of the society they wish to create; however, in practice, it is often constrained by the socio-political realities of individual national cultures. In order to regulate the real world of human behavior whenever it is viewed as inconsistent with the model world, these rules and regulations are judiciously interpreted and applied through a system of courts to negotiate and invariably enforce desired behavior. The so-called model world is thus created by imposing rights and obligations, permissions and prohibitions through legislation, and this, in most Western democratic systems, is seen as the will of the elected representatives of the people in the parliament. However, Bhatia (1993: 102) points out:

> As legal draftsmen are well aware of the age-old human capacity to wriggle out of obligations and to stretch rights to unexpected limits, in order to guard against such eventualities, they attempt to define their model world of obligations and rights, permissions and prohibitions as precisely, clearly and unambiguously as linguistic resources permit. Another factor that further complicates their task is the fact that they deal with a universe of human behavior, which is unrestricted, in the sense that it is impossible to predict exactly what may happen within it. Nevertheless, they attempt to refer to every conceivable contingency within their model world and this gives their writing its second key characteristic of being all-inclusive.

This view of law and legal justice gives legislation the status of primary legal genre, which is essentially written "with mathematical precision, the object (though not always attained) being, in effect, to provide a complete answer to virtually every question that can arise' (Sir Charles Davis, quoted in Renton,

"*Cognito verborum prior est, cognito rerum postior est*," said Erasmus. If the knowledge of law is more 'potent,' the knowledge of language is 'prior.' Language undoubtedly plays an important role in the construction, interpretation, negotiation, and implementation of legal justice. It is through a variety of legal genres that an attempt is made to create and maintain a model world of rights and obligations, permissions and prohibitions. In principle, this model world is designed to be consistent with the vision that individual states or nations have of the society they wish to create; however, in practice, it is often constrained by the socio-political realities of individual national cultures. In order to regulate the real world of human behavior whenever it is viewed as inconsistent with the model world, these rules and regulations are judiciously interpreted and applied through a system of courts to negotiate and invariably enforce desired behavior. The so-called model world is thus created by imposing rights and obligations, permissions and prohibitions through legislation, and this, in most Western democratic systems, is seen as the will of the elected representatives of the people in the parliament. However, Bhatia (1993: 102) points out:

> As legal draftsmen are well aware of the age-old human capacity to wriggle out of obligations and to stretch rights to unexpected limits, in order to guard against such eventualities, they attempt to define their model world of obligations and rights, permissions and prohibitions as precisely, clearly and unambiguously as linguistic resources permit. Another factor that further complicates their task is the fact that they deal with a universe of human behavior, which is unrestricted, in the sense that it is impossible to predict exactly what may happen within it. Nevertheless, they attempt to refer to every conceivable contingency within their model world and this gives their writing its second key characteristic of being all-inclusive.

This view of law and legal justice gives legislation the status of primary legal genre, which is essentially written "with mathematical precision, the object (though not always attained) being, in effect, to provide a complete answer to virtually every question that can arise' (Sir Charles Davis, quoted in Renton,

1975). It is hardly surprising that this legal genre has its own unique integrity and identity, often characterized by its use of a number of lexico-grammatical and discoursal resources that are rarely used in any other disciplinary or professional genre. As documented in Bhatia (1982, 1993), this genre is characterized by the use of a complex array of qualifications, often strategically positioned at syntactic points where they are unlikely to attract any ambiguous or unintended interpretation. The *Renton committee report* (1975) also emphasizes this aspect of legislative genre:

> Ordinary language relies upon the good offices of the reader to fill in omissions and give the sense intended to words or expressions capable of more than one meaning. It can afford to do this. In legal writing, on the other hand, not least in statutory writing, a primary objective is certainty of legal effect . . . Parliament seeks to leave as little as possible to inference and to use words which are capable of one meaning only.

The use of qualifying expressions is thus a pervasive phenomenon in legislation. They are more central to the rhetorical structure of legislative sentences and thus form the basis of the underlying 'cognitive structuring' (Bhatia, 1982). They seem to provide the essential flesh to the main proposition in the legislative provision, without which it will be like a mere skeleton of relatively modest legal significance. Qualifications thus form an important part of the linguistic repertoire of the legal draftsman. This may also be due to the fact that qualifications, particularly (complex) prepositional phrases and various subordinate clauses, are syntactically highly mobile, and the legal draftsman tends to take full advantage of their mobility to insert them at various syntactic positions to achieve the desired level of precision and unambiguity.

Precision, especially as a function of adequate specification of legal intentions, is achieved through the use of a variety of legal qualifications (Bhatia, 1982), some of which are used to describe the case(s) to which a particular legislative provision applies. Others are used to impose conditions on the application and implications of the provision, in particular when it comes to the resolution of potential or real conflicts between different legislative acts (see Bhatia, 1982 for details). Qualifications thus form the basis of the underlying cognitive structuring in legislative sentences. They seem to provide the basis for legal specification as emphasized by Caldwell, an experienced parliamentary council in the United Kingdom:

> . . . if you extract the bare bones . . . what you end up with is a proposition which is so untrue because qualifications actually negative it all . . . it's so far from the truth . . . it's like saying all red-headed people are to be executed on Monday, but when you actually read all the qualifications, you find that only one per cent of them are . . . (qtd. in Bhatia, 1982)

To illustrate this aspect of legislative provision, let me consider the following example:

> If in the course of winding up a company it appears that any person who has taken part in the formation or promotion of the company, or any past or present officer or liquidator or receiver of the company, has misapplied or retained or become liable or accountable for any money or property of the company, or been guilty of any misfeasance or breach of duty in relation to the company which is actionable at the suit of the company, the court may, on the application of the Official Receiver, or of the liquidator, or of any creditor or contributor, examine into the conduct of the promoter, officer, liquidator or receiver, and compel him to repay or restore the money or property or any part thereof respectively with interest at such rates the court thinks just, or to contribute such sum to the assets of the company by way of compensation in respect of the misapplication, retainer, misfeasance, or breach of trust as the court thinks just. (Hong Kong SAR, 1997: Companies Ordinance (Section 276))

If we ignore the qualifications in this provision, we find the court being assigned unlimited powers to "examine into the conduct of the promoter, officer, liquidator or receiver, and compel him to repay or restore the money or property or any part thereof . . . to the assets of the company." However, the moment we take into account all the qualifications that have been positioned at various syntactic points, we notice that the court's powers are not so widely applicable. Firstly, the court can take action only when a specific number of conditions meet within the context of a case description, that is, the winding up of a company; and then there are numerous conditions on its application, such as the involvement and participation of specific descriptions of people in the formation or promotion of the company; also, their actions must be disadvantageous to the company. If all these conditions are met, then the court can exercise the power to examine into the conduct of these persons and compel them to compensate the company. What seemed an unlimited power to the court without the qualifications turns out to be a rather modest authority to examine the conduct of a few officials of the company under specific conditions. Such is the role and function of qualifications in the legislative genre.

Precision is also achieved through the use of nominalized expressions, which is often achieved by converting verbal expressions into nominalizations, as underlined in the following example from the *Wills act* from the Republic of Singapore:

> No obliteration, interlineation or other alteration made in any will after the execution thereof shall be valid or have effect except so far as the words or effect of the will before such alteration shall not be apparent, unless such alteration shall be executed in like manner as hereinbefore is required for the execution of the will; but the will, with such alteration as part thereof, shall be deemed to be duly executed if the signature of the testator and the subscription of the witnesses be made in the margin or on some other part of the will opposite or near to such alteration or at the foot or end of or opposite to a memorandum referring to such alteration and written at the end or some other part of the will. (Government of Singapore, 1970: Section 16 (underlining added))

As each rule of law is essentially encoded in a single-sentence legislative provision, it often contains repetitions of actions and concepts. For the sake of avoiding any potential ambiguity of reference, nominalizations are seen as a useful syntactic resource to facilitate precision in such rhetorical contexts.

Precision and clarity are also achieved through the use of "complex prepositional phrases" (Quirk *et al.*, 1982: 302), such as *in pursuance of*, *in accordance with*, *by virtue of*, *for the purpose of*, and several other combinations of preposition-noun-preposition (P-N-P). Legal draftsmen are particularly suspicious of simple prepositions, as they find them potentially ambiguous in meaning, and hence often go for complex prepositions, many of which are rarely used in any other variety of professional discourse.

In addition to precision and unambiguity, legislative genre is notorious for being all-inclusive as well. This quality of all-inclusiveness is often achieved through the use of what is referred to as binomials and multinomials, as illustrated in the following example from the U.K. *Litter Act* of 1958:

> If any person throws down, drops or otherwise deposits in, into or from any place in the open air to which the public are entitled or permitted to have access without payment, and leaves, any thing whatsoever in such circumstances as to cause, contribute to, or tend to lead to, the defacement by litter of any place in the open air, then, unless that depositing and leaving was authorised by law or was done with the consent of the owner, occupier or other person or authority having the control of the place in or into which that thing was deposited, he shall be guilty of an offence and be liable on summary conviction to a fine not exceeding ten pounds; and for the purpose of this subsection any covered place open to the air on at least one side and available for public use shall be treated as being a place in the open air. (*Litter Act,* 1958 (underlining added))

This short paragraph is interesting in two rather different ways. Through the use of multinomials (Gustafsson, 1984) such as *throws down, drops or otherwise deposits*, *in, into or from*, *entitled or permitted*, *to cause, contribute to, or tend to lead*, the draftsman makes it possible for anyone to be guilty of littering at least in 72 different ways. The use of multinomials brings not only precision but also all-inclusiveness in the specification of legal scope. The other device that makes such a construction interesting is the use of all-inclusive expressions of a different kind, such as '*any thing whatsoever,*' '*otherwise* deposits,' and '*any* covered place.' Although these expressions are often viewed as indicators of vagueness and hence lacking in precision in a traditional sense, they bring all-inclusiveness of a different kind to the provision. The legislative genre thus appears to be extremely versatile, using not only precision and all-inclusiveness, but also vagueness and indeterminacy for the required specification of legal intentions.

Legislative genre is also unique in yet another way, that is, it has a typical cognitive structuring that can be characterized by the following rhetorical structure:

> If X, then Y shall do Z.

where X is the description of the case to which the provision applies; Y is the legal subject who is given the power or authority to act, or is prohibited from acting in one way or the other; and Z is the legal action that is either permitted, authorized, or prohibited. This can be illustrated by the following example.

> If *a police officer fails to follow the proper procedures stated in this section 1 above*, (X)
> then *the person affected by this failure* (Y)
> shall *apply to the court for the protection of his interests.* (Z)

Legislative genre thus has a 2-part rhetorical structure consisting of a case description and the legislative provisionary action, which include both the legal subject and the legal action. This form of rhetorical structuring linking case description to specific legislative action also makes an interesting link with the other set of legal genres such as judgments and cases, which are viewed as applications of legislative intentions to interpret and change, wherever necessary, the real world in line with the ideal world as envisioned through legislative procedures. These secondary genres are also seen as illustrations of professional reasoning and use of appropriate authorities either in favor of or against a particular judicial decision. Often these decisions are used as precedents in common-law jurisdictions and hence acquire the status of legal authorities, just like the legislative provisions. As Bhatia (1993: 175) points out:

> Legal cases and legislation are complementary to each other. If cases, on the one hand, attempt to interpret legal provisions in terms of the facts of the world, legislative provisions, on the other hand, are attempts to

account for the unlimited facts of the world in terms of legal relations.

In order to fully understand the nature and function of argumentation in legal cases, it is important to understand the relationship between different forms of legal discourse, such as the legal judgment and legislative provision, on the one hand, and the facts and events of the real world and the legal intentions and sociopolitical values and constraints as part of the model world, on the other. The two sets of relationships are mediated through legal reasoning and precedence within a particular legal framework, without which it is impossible to construe application and interpretation of legislation, including rules, statutes, regulations, and ordinances.

There is also an interesting parallel between legislation and judgments as instances of legal genres. Legislation consists of two main rhetorical moves, that is, case description and the legal action; similarly, a law case typically begins with the establishing of facts and ends with a judgment that invariably indicates the kind of legal action imposed by the decision of the court. Often there is also an attempt to derive what in legal language is called *ratio decidendi,* which is a kind of formulation of legal principle that becomes a precedent for subsequent cases of similar description. These unprecedented parallels between the two genres are not purely coincidental. The judgment is the result of a logical argument based on evidence presented in the court and argued and interpreted in the light of rules and regulations as well as precedents from earlier judgments. This can be represented as shown in Figure 1.

Judgments and cases are thus the written records of negotiation of justice, which can be viewed as attempts to enforce legislative intentions to bring the real world closer to the model world. A law case is essentially an abridged version of a judgment of a particular judge or a bench based on the actual negotiation of justice in a court of law. Judgments are public documents and are taken as records of court proceedings intended for use as precedents for subsequent judgments, especially in common-law jurisdictions. Cases are used in academic settings to demonstrate the nature and logic of judicial reasoning in the negotiation of justice. As indicated in Bhatia (1993: 118):

> Legal cases are used in the law classroom, the lawyer's office and in the courtroom as well. They are essential tools used in the law classroom to train students in the skills of legal reasoning, argumentation and decision-making. Cases represent the complexity of relationship between the facts of the world outside, on the one hand, and the model world of rights and obligations, permissions and prohibitions, on the other.

Language is used precisely, clearly, and unambiguously in legislation as well as in judgments; however, in legislation every effort is made to make it all-inclusive as well, whereas in judgments an attempt is made to interpret all-inclusiveness in the light of the specific facts of the case. The relationship between the two genres thus is one of construction of principles and application of such principles. The following brief example of a case cited in Bhatia (1993: 120) will illustrate this relationship:

> Roles v. Nathan (1963) I W.L.R. 1117
> Two chimney-sweeps were killed by carbon monoxide emitting from the ventilation system of the boiler on which they were working. They had chosen to ignore a prior warning of this danger. The Court of Appeal held that the defendants were liable, for, in the words of Lord Denning M. R., "When a householder calls in a specialist to deal with a defective installation on his premises, he can reasonably expect the specialist to appreciate and guard against the dangers arising from the defect." (Bradbury, 1984: 107)

As argued in Bhatia (1993), rhetorical structure for legal cases often includes four moves: case identification, case description (establishing facts), argument, and judgment (which may often include *ratio decidendi*) (see Table 1).

It is interesting to note that legal cases in their most abbreviated forms will essentially include the case description and the legal action applicable to such a description of legally material facts. This essential 2-part rhetorical structure is remarkably similar to the one in the legislative genre. Even when analyzing *ratio decidendi*, we still find a similar 2-part rhetorical structure (see Table 2).

Figure 1 Intertextual relations in legal genres.

There is another parallel genre related to written judgment, and that is the negotiation of justice in the courtroom, mediated through the spoken mode. Widely familiar as courtroom interaction, this represents a legal genre embedded in a formalized professional legal setting and is employed to negotiate and maintain social relations through the questioning of witnesses. Although the main participants are the counsel, the witnesses, the jury, and the judge, the major part of interaction involves the examination and cross-examination of witnesses by the two counsels to bring to light the facts of the case, that is, to identify and establish the legally material facts of the case, which are crucial to the description of the case in question. The outcome of questioning as part of the direct and cross-examination thus is as much a function of the contributions made by these two participants, that is the counsels and the witnesses, the verbal strategies employed by them, and the degree of credibility established by them as it is of the supposed facts of the case. Facts therefore are not simply an objective phenomenon in this setting. They are constructed as a result of the questioning. However, it is interesting to note that the courtroom questioning strategies are primarily employed to win cases, not to help the jury and the judge to discover and establish facts. Counsels thus do not present facts as they might be, but they do so as they want the court to see them. This brings in the role of language and control, over not only what the counsel says but also over what the witnesses might say.

All of this interaction takes place in a very formal organizational context, where forms of behavior, turn taking, participant roles, questioning and responding strategies, and even the content of questions and responses are all tightly controlled by the conventions established and enforced by the courts. The conventions are meant to ensure that courtroom examination of witnesses is carried out in formal language strictly enforcing not only turn taking but also the type of speaking that is allowed. The counsels, for instance, are only allowed to ask questions that are specific, answerable, and designed to elicit the evidence or statements of facts related to the case; and the witnesses, for their part, are required to answer these questions appropriately and truthfully, often with a 'yes' or 'no.' The counsel who is not engaged in questioning at a particular time is allowed to make objections where he feels that inappropriate evidence is being offered or rules being violated, but the judge decides whether the objections are valid or not.

By definition there are two participants, the prosecution v. the defense, and in the end, one wins and the other loses. Although the jury and the judge often make the decision, they cannot actively participate in the court proceedings. Just like any other 2-party interaction, the courtroom examination of witnesses gives counsels more liberty to talk, interrupt, control resumption of talk, and introduce new topics. In addition, they even are allowed to a large extent to control the responses of the witnesses. Witnesses tend to acknowledge this kind of control by copying the question in their answers. If they are not able to control the witnesses' responses, they tend to destroy the witnesses' credibility by showing contempt for them. However, clever witnesses can sometimes make attempts to minimize the effects of such attempts. All this can be perceived as a game being played almost entirely by the counsels, who are the primary players. Witnesses know relatively little about the procedures of the court, including their own contributions, especially as to how these are interpreted, what effect their contributions will have on the jury or the judge, or on the outcome of the trial (Bhatia, 1997). This is well illustrated by the following example of an account of courtroom interaction from Allen and Guy (1989), provided by Worthington through personal communication in 1984:

Table 1

Roles v. Nathan (1963) I W.L.R. 1117	*Case identification*
Two chimney-sweeps were killed by carbon monoxide emitting from the ventilation system of the boiler on which they were working. They had chosen to ignore a prior warning of this danger.	Case description
The Court of Appeal held that the defendants were liable, for, in the words of Lord Denning M. R., *"When a householder calls in a specialist to deal with a defective installation on his premises, he can reasonably expect the specialist to appreciate and guard against the dangers arising from the defect."*	**Legal action** *(ratio decidenti)*

Table 2

When a householder calls in a specialist to deal with a defective installation on his premises, **he can reasonably expect the specialist to appreciate and guard against the dangers arising from the defect.**	Case description **Legal action**

> An off-duty policeman in a store had shot and killed an intruder. Investigation had shown a set of burglar tools at the back of the store. The prosecutor was trying to show that there was no ground for presuming criminal intent, and that this was cold-blooded murder. The victim's wife was testifying for the prosection. Here she is being cross-examined by the defense.
>
> *Defense Lawyer: Could you tell the court and the jury what your husband's occupation was?*
> *Wife: He was a burglar.*
>
> This supported the defense's contention of criminal intent, and secured acquittal for the policeman. (Worthington, 1984, personal communication)

If only the wife had been slightly more familiar with the conventions of the courtroom examination, the task of the defense lawyer would not have been that easy. Another illustration of unfamiliarity with legal conventions and ignorance of legal knowledge on the part of witnesses in courtroom examination comes from the following supposedly made-up interaction (source unknown) between the witness (W), counsel (C), and judge (J):

> *W: That dirty double-crosser John deceived me.*
> *C: Your honor, I object.*
> *J: Objection sustained. Now try to tell the court exactly what happened.*
> *W: He double-crossed me, the dirty lying rat.*
> *C: Your honor, I object.*
> *J: Objection sustained. Will the witness try to stick to the fact?*
> *W: But I am telling you the fact, your honor. He did double-cross me.*

The nature and degree of control in the use of language in this derived unequal interaction in the courtroom is also confirmed in the advice that Wellman (1997) seems to have for specialists in cross-examination:

> In all your cross-examination, never lose control of the witness; confine his answers to the exact questions you ask. He will try to dodge direct answers, or if forced to answer directly, will attempt a qualification or explanation which will rob his answer of the benefit to you. (Wellman, 1997)

Conclusions

Genres are products of disciplinary cultures and as such they are constructed, interpreted, and exploited to achieve disciplinary objectives. From the foregoing discussion of the nature and function of legal genres, it is obvious that the most central concern in legal writing is the specification of legal intentions in a clear, precise, unambiguous, and all-inclusive manner, and that the legislative genre is the most central and dominant form of such expression. The other legal genres, such as judgments and cases in the written mode, and courtroom interaction (direct and cross-examination) in the spoken mode, may be viewed as derived genres, the main purpose of which is to negotiate, document, and report judicial processes and decisions, which are based on appropriate interpretations of legislative intentions. Since these derived genres, whether in spoken or written mode, are often based on interpretations of explicit and precise legislative intentions, they are likewise characterized by precise, clear, and unambiguous expressions of certainty in legal effect. This is also signaled in a complex and often dynamic interplay of 'intertextuality' and 'interdiscursivity' (Bhatia, 2004) in the construction of these derived genres.

There are two more sets of legal genres that form the complete 'system' of legal genres, the target genres and the enabling academic genres (Bazerman, 1994). The target genres are once again based on the interdiscursive formations of legislative and judicial expressions, and therefore share the same concerns of clarity, precision, unambiguity, and all-inclusiveness, leading to certainty of legal effect. These include a range of professional genres such as property conveyance documents, contracts, and agreements, including insurance documents, court case documents, and affidavits of various kinds. These are both the products as well as the instruments of legal practice. We also find a range of academic legal genres that are used to train legal professionals within the academy as well as at the interface between the academy and the professional practice, which include textbooks, legal problems, moots, examination essays, legal memoranda, critical essays, problem-solving essays, pleadings, and so forth. To sum up, I have proposed legislative provisions as the primary legal genres, which forms the basis and essence of all legal conceptualizations and practices. I then proposed a set of secondary genres, such as judgments and cases, which are the written reports of judicial processes and negotiations of legal justice; their counterparts in spoken form are courtroom interactions, which include several genres, as well as direct and cross-examinations in the courts of law. The second category of derived genres I have termed target genres, which again share a number of linguistic as well as legal characteristics with the other legal genres. Finally, I identified a set of enabling genres far richer in intertextuality and interdiscursivity than most of the primary or secondary (derived as well as target) genres. These are largely confined to the academic settings used for training and educational purposes. The main purpose of these pedagogic genres is to explain and interpret the model world of rights and obligations, permissions and prohibitions in the context of the real world that we live in,

Figure 2 Genre systems in law.

to train legal professionals to be able to participate in legal practice, and to handle various primary as well as secondary genres. The complete system of legal genres can be summed up as shown in Figure 2.

Legal Language: History

H E S Mattila, University of Lapland, Rovaniemi, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

This article makes visible the history of legal language through examples taken from various European tongues, some of them major, some minor. A few references are also made to non-European tongues. Because legal terminology always reflects the conceptual system of the law, it is impossible to avoid entirely dealing with the history of legal systems. The following presentation concentrates on modern history (to the present), but some examples date back to the period of archaic law and to Roman and Medieval times. In order to treat logically the complex and heterogeneous materials in the field, the article is divided into three parts: (1) the rivalry between major legal languages, (2) legal language and linguistic interaction, and (3) the intelligibility of legal language. Many interesting aspects (e.g., the transition from oral language to written language in law) are found elsewhere (*see* **Language of Legal Texts**).

Rivalry between Legal Languages

Language is power, and legal language, used by state administration and by law courts, is an instrument of power *par excellence*. This is why all strong rulers have aimed at spreading their own tongue into internal and international legal use. The Romans succeeded very well in spreading Latin, and the dominance of legal Latin continued in Europe throughout the Middle Ages, mostly due to the administrative needs of the Catholic Church. After the displacement of Latin in legal activities at the beginning of modern times, a struggle between modern legal languages begun.

Legal Latin and the Vernaculars

The Medieval Dominance of Latin The great common denominator of all European legal cultures is Roman law and its language, Latin, used in law irrespective of the language of the people. After the collapse of the Western Empire, this was first visible in the former eastern parts of the Roman Empire. The early Byzantine Emperors used Latin in their administration, and the great codification of Roman law of Emperor Justinian, later called *Corpus juris civilis*, was essentially edited in Latin. In the course of time, the Byzantine administration and law became entirely Greek even though Latin loan words remained in legal use.

It is easy to understand that Latin was quite quickly given up in the Byzantine Empire because it had to compete with an older cultural language, Greek, that had a status comparable, if not superior, to Latin. In contrast, in the regions of the defunct Western Empire there were, in the beginning, no written languages based on the vernaculars. Even much later, after the creation of new written languages, the authority and the use value of Latin was still overwhelming. Latin was the original language of Roman law, researched in every university and directly or indirectly applied by the courts of many countries. Simultaneously, Latin was needed in administrative matters crossing linguistic borders. Latin was particularly the language of the central administration of the Catholic Church, used in its legal order, canon law, which was largely based on Roman law. It is worth noticing that Latin was also one of the old languages of the common law of England, in spite of the native origin of this law. But the dominance of Latin was not absolute in the Middle Ages. On the coasts of the Baltic Sea, for instance, it has to compete with Low German in legal activities.

Switch over to National Languages Generally speaking, the switch from Latin to the national languages of the various countries was very slow in the field of law. This switch was especially slow among academic jurists. In many European countries, the 17th and the 18th centuries were still part of the golden age of legal literature in Latin, and important legal works in Latin were published even later. This was in part due to the rules of the universities.

In the field of international legal affairs, Latin was the language of negotiations and treaties until the 17th century, when French started to replace it. This replacement was due to the strengthening of France as a great power in relation to the Holy German Empire and to the Pope, both having usurped Latin as their language. There was much resistance (by the German Empire and other countries) to the use of French in diplomacy and international law: Giving up Latin meant at the same time giving up the principle of linguistic neutrality and equality in the relations between states.

In the field of internal legal matters, the records and decisions of law courts, administrative authorities, and notaries were often drawn up in Latin in the Middle Ages, and, in some countries, they still were at the beginning of the modern era. This also applied to statutes. Differences between individual countries were, it is true, considerable. In some countries, the vernaculars were used in addition to or instead of Latin. In the royal law courts of France, for instance,

French had already become the language of the proceedings at the end of the Middle Ages.

In central Europe, but also in other regions, particularly in Italy, the position of Latin as the language of legal activities was strong until the 18th and 19th centuries. This was due to Humanism, to the reception of Roman law, and to academic traditions. If canon law is not taken into account, Latin was used in practical legal activities for the longest time (until the middle of the 19th century) in certain parts of the Austrian Empire: in Croatia, Hungary, and southern Poland (Galicia). In Hungary and Poland, it was a safeguard against the Germanization of these regions and, in Croatia, paradoxically, against the Magyarization of the country.

Today, Latin still is the authentic language of the legal system of the Catholic Church, canon law. The jurisdictions of this Church used only Latin until 1917; the vernaculars were then introduced into ecclesiastic legal matters. Even though the *Codex juris canonici* (1983) now in force also exists in the vernaculars, the sole Latin text of this codification is legally binding.

Rivalry between Vernaculars (Modern Legal Languages)

Rivalry within State Boundaries After the displacement of Latin, the rulers of the new national states aimed at stabilizing their superiority in relation to local power centers by different means, among others by the use of a single language. France is a good example of this. French, originally a Romance dialect of Île-de-France, was made the official language of the kingdom by a number of royal ordinances at the end of the 15th century and the beginning of the 16th century. In addition to eliminating Latin, these ordinances, among other things, put an end to the use of Occitan (Languedocien) in the courts of law of the Midi. In addition to language legislation, the founding of new high courts had a key role in turning the recently conquered territories of the kingdom French. Modern examples are numerous, for example, the use of legal Russian in the Soviet Union.

Sometimes there have been – and still are – cases of bitter rivalry between two variants of a same language in legal activities. Greece, in particular, is worth mentioning. The official language, and consequently also the legal language, of this country was, from the 19th century until the fall of the military junta (1974), Katharevusa, a variant of Modern Greek that conserves important elements of the classical language. Attempts (also in law) to replace this variant with Demotic Greek, which is closer to today's spoken language, were made from the beginning of the 20th century. They succeeded only in the 1980s after a period of approximately 10 years of bitter language struggle. In Norway, a similar competition between two language variants (one, Bokmål, based on Danish, a cognate language; the other, Nynorsk, based on West Norwegian dialects) has been going on for over 100 years.

International Rivalry In the modern era, European legal languages began to spread to other continents due to colonial expansion. This was particularly the case of both the Americas, where Spanish, Portuguese, French, and English were used in legal activities. Changes in the possession of colonies, for example, in Quebec, caused different sorts of rivalry. An important part of the struggle between great legal languages has always taken place in the field of international relations: diplomacy and treaties between states. In this field, the rivalry between French and English over the past few centuries has been of global importance. After having gained the position of the leading great power in the 17th century, France spread its language into many fields, particularly into international relations. After Latin, the French language dominated this field for a long time.

This dominance started to break down during the second half of the 18th century and more clearly in the beginning of the 19th century, after the defeat of Napoleon Bonaparte. However, the position of French as an international language of diplomacy and treaties did not become really threatened until much later, in the 20th century, due to the explosive increase in the use of English in this field.

The 20th century may be characterized in international legal activities as a period of transition from monolingual French dominance to the bilingual use of French and English and more recently to the monolingual English dominance. Originally, French was the leading working language of the European Communities (now the European Union); today both French and English (and, less frequently, German) are used as working languages in the institutions and organs of the European Union. The Court of Justice excepted (French is the sole language of internal working of the court), some of these bodies use mostly English, and this tendency is strengthening.

Legal Language and Linguistic Interaction

Interaction between Legal Language and Common Parlance

The Two-Way Traffic between Legal and Common Vocabulary After social or political changes in different times, new vernaculars have been brought into public use. It has then been necessary to create legal languages based on these vernaculars, for example,

the creation of the Romance legal languages in the Middle Ages. Later examples are numerous. In Finland, Swedish was the sole official language of the country until the second half of the 19th century. When Finnish also gained official status in Finland at the end of that century, legal Finnish had to be created: a great number of common parlance words were given exact legal definitions, which made possible their technical use in law. Even more recently, democratization processes have resulted to the creation new legal languages. The best example, perhaps, is the Republic of South Africa where there now are 11 official languages, most of them African (Zulu, Xhosa, Sesotho (Sotho), etc.) used in administrative and judicial matters. A great deal of time has lately been spent on developing administrative and legal terminology for these African languages.

As well, the creation of a new legal language has often been an important factor in establishing the written language of the country, in general. This is clearly shown by the development of written French at the end of the Middle Ages. A high court, *Parlement de Paris*, originating from the King's Council, started its activities as a judicial organ in the middle of the 13th century. It worked in French from the very beginning, constantly creating new words for its purposes. Gradually, a great number of these words were transferred to the written language of other fields and also to common parlance. Some orthographic practices of French are also derived from the old judicial language. In this way, the language of law has played an important cultural role in many countries.

Conservatism and Radicalism in the History of Legal Language Having been established, legal language has normally been conservative: Its development has been slower that that of the written language in general. Therefore, the legal language, especially legal terminology, sometimes is almost a language museum. This is clearly demonstrated by legal English. The situation in Greece (mentioned previously), on the other hand, shows that the language used in legal activities may be brought closer to the common parlance if the distance between written and spoken language grows too much.

Occasionally conservatism, the typical feature of the language of law, has changed into a radical reformation of legal terminology. This has happened in connection with social crises and revolutions. For example, during the French Revolution, the old legal terminology expressing feudalism was replaced by terms expressing the values of the bourgeoisie. Another good example of this kind of radical change in terminology occurred during the first years of the Soviet state, when the terminology of legal Russian was entirely reformed because the Bolshevik leadership felt that it was not in harmony with the new spirit of the time. For instance, the term *prestuplenie* 'crime' was replaced by the expression *sotsialno opasnoe deistvie* 'socially dangerous activity'. However, this change was only temporary. Later, legal Russian again became more conservative and numerous prerevolutionary terms were restored, and, during the last decades of the Soviet *régime*, Russian legal linguists emphasized that the language of law must be stable and that no linguistic experiments should be allowed in statutory texts.

Interaction between Legal Languages

The Transfer of Legal Expressions from Latin to Modern Languages During the long transition period from legal Latin to modern legal languages, much of the Latin legal vocabulary was borrowed by these languages. In the Romance languages and in English, Latin words were often adopted with minor orthographic changes. In other languages (German, the Scandinavian languages, the Slavic languages, etc.), loan translations were more common. Everywhere, many loaned senses of Latin words were taken into the modern languages. In addition to these borrowings, a great number of direct Latin citations continued to be used in modern legal languages. During the first centuries of the transition, these citations were so common that legal texts often were a hybrid language in which Latin and the modern tongue alternated. This is visible even today. According to one author, Latin terms and maxims belong to the "beloved folklore" of the lawyers.

Borrowings between Modern Legal Languages Latin has not been the sole source of legal loan words. The French language has also been particularly important during several epochs. Because French was from the 13th century until the end of the 14th century (and also partly into the 15th century and even until the 18th century), one of the languages of law in England, a huge number of French words were transferred into the English legal vocabulary (most being ultimately derived from Latin). Similarly, after the rise of France to the position of the dominant great power in Europe in the 17th century, several legal languages adopted many of the French terms from public and private international law. Many of these were direct citations: *lettres de créance*, *renvoi*, *ordre public,* and so on. In the very recent history, a new wave of French lexical influence is perceivable in the activities of the European Union. For instance, the term *acquis communautaire* has been adopted in all the languages of the member states, either in the form

of a direct citation, of a loan word, or of a neologism based on the French expression.

The end of the 19th century was the golden age of German legal science, having great influence all over Europe, even in North America. Due to this influence, a number of German citations and loan translations related to the activity of different schools of legal science, among other things, spread into international use: *Begriffsjurisprudenz, Pandektenrecht,* translations of *Rechtsgeschäft,* and so on.

In the 19th and 20th centuries, English became the most important language of international commerce and commercial law, also used by non-Anglophone contract parties. Much of the English terminology for commercial law was borrowed by other languages. During the past few decades, the same phenomenon can be seen in other modern fields of law, due to the influence of American legal institutions in all countries.

Borrowings between European and Non-European Legal Languages Borrowings between European and non-European legal languages had already appeared in antiquity. With the spread of Christianity, loan words from Hebrew were transferred into European legal languages. Later on, some words of Arabic origin were adopted into these languages, for example, *avarie* and *douane* in French (through Italian). In the opposite direction, the influence of Greco-Roman legal thinking on the formation of early Islamic legal concepts, although disputed, is probable.

In the modern era, European legal languages have strongly influenced a great number of non-European legal languages. The tongues of the colonial powers (Dutch, English, French, Portuguese, and Spanish) were regularly used in the administration of their possessions in the Americas, Africa, and Asia and in the legal proceedings there. When these possessions became independent states and their legal languages were created and developed, the terms expressing European legal concepts were direct citations, words of foreign origin, or loan translations from European languages. In Indonesia, for instance, numerous Malay (Indonesian) law terms were created on the basis of legal Dutch: *kasasi* 'cassation, annulment', *eksekusi* 'enforcement', and so on.

Lexical borrowing from non-European legal languages into European legal languages has happened less frequently in recent history. However, loan words are frequent in cases in which European legal languages are used in non-European context, for example, in legal texts in which Islamic law is described or applied in English or French. Indian treatises of Islamic law are teeming with terms such as *hiba, khula,* and *mutwalli*. The same can be said about North African treatises in French.

Borrowing of Style Features between Legal Languages Many stylistic features in European legal languages are derived from the style of Medieval Latin documents, often drawn up by the administration (the judiciary included) of the Catholic Church. Indeed, the importance of papal curia in the development of coherent administrative Latin in the Middle Ages was crucial. Its language strongly influenced secular chanceries, courts, notaries, and other organs all over Europe. The language of the administration and the judiciary of the Catholic Church was highly developed. It was by far technically superior to the language of secular organs. Therefore, it became a paragon to be imitated by these organs. Some of the stylistic features of Medieval legal language have persisted for a very long time, for example, the use of long and complicated sentences. Language specialists have to fight against this stylistic feature even today.

In certain respects, the styles of the European legal cultures have grown in different directions, due to divergences in legal history. It is particularly striking that there are, in various countries, large differences in the drawing up of legal documents. The best example is the decisions of high jurisdictions: the style of these decisions (structure, references to other texts, length of sentences, formulation of votes, etc.) is strictly bound by the tradition of the particular country.

The Intelligibility of Legal Language

The Tradition of Obscurity

Throughout history, legal language has been difficult to understand. This is self-evident when a language totally foreign to the population has been used, and it is also clear when legal language has been spiced with a great number of words of foreign origin. But, in addition, lawyers have traditionally used complex expressions and sentences in their documents due to the rituality and technical refinement of the law.

Use of Foreign Languages and Terms of Foreign Origin In all times, languages not known by the local population have been used in law and administration because of the interests of the central power, which was frequently multiethnic. Simultaneously, the use of such languages has been supported by the growth of legal professionalism. The Medieval lawyers had a corporative interest in acquiring and holding the monopoly on knowledge in legal matters. This was guaranteed by their use of languages incomprehensible to ordinary people.

As already pointed out, the most important cipher throughout Western legal history has been Latin. In the Middle Ages, legal proceedings were often carried on in Latin even when the accused was ignorant of this language, and even later, in early modern times, court decisions were sometimes written in Latin. Hence, the application of the law was incomprehensible to ordinary people – and, due to this, impressive and frightening. In addition to Latin, other foreign tongues were used as well. In Medieval England, law French was one of the legal languages, and, to take a more recent example, the judiciary of Finland used only Swedish until the second half of the 19th century. Even after the transition to using the language of ordinary people in administrative and judiciary matters (and even today, this has not happened everywhere), the intelligibility of legal language has been – and still is – hindered by legal terms derived from foreign languages, especially from those that were used in earlier periods (Latin, law French, etc).

Rituality and Technical Refinement The maintenance of the authority of the state has always been one of the major functions of the law. In this purpose, the state has throughout the history emphasized the sacredness of the law, and often connected it with magical elements. Ritual language has been used (e.g., in oaths) to strengthen this effect. Even today, this is clearly discernible in legal English: repetitions and binary expressions are typical of this language, making legal texts complicated and often difficult to understand.

In more developed societies, the complexity of legal language was increased by the birth of the legal profession and the growth of the technicality of the law, connected with the demands of exactitude and legal safety. The development of the Latin notary institution, first in Italy and then in other countries, in the beginning of the 2nd millennium had this kind of effect. The legal documents drawn up (in Latin) by notaries were more technical and complicated than earlier documents. In England, common law grew as case law. The development of this kind of law required subtle distinctions between different cases, that is, between their facts and circumstances. The conceptual system of common law therefore became very complicated. This system, again, required a complex terminology, and within this framework each term had to be interpreted in a narrow way. Simultaneously, the completeness of common law, as finely built case law, presupposed that detailed situation combinations were taken into account in all legal texts. As a consequence, common-law statutes and contracts have always been – and still are – very complicated and verbose.

The Growth of the Concern for the Quality of Legal Language

All the phenomena mentioned so far – the strengthening of the authority of the law by using language rituals, the complexity of the law due to its growing technicality, and the use of terminology of foreign origin – have made legal language difficult to understand even when it has coincided with the tongue of the people. Therefore, demands for simplifying legal language have been made throughout the ages.

However, the first serious measures to create plain legal language were only taken during the Enlightenment (18th century). This took place mostly in the German language area. The famous Prussian codification of 1794, *Allgemeines Landrecht für die preussischen Staaten*, is a major monument of the plain language planning of the epoch. This codification aimed at stylistic clarity. It also avoided words of foreign origin: Such words are much less frequent in the *Allgemeines Landrecht* than in earlier Prussian statutes. The concern for the quality of legal language in the Enlightenment was down-to-earth but prejudiced. In Hungary (then a part of the Austrian Empire), for instance, an intelligibility test was in use: Statutory drafts were shown to an ordinary subject, unhesitatingly called *buta ember* 'stupid man', in order to see how much of them he could understand. These Enlightenment ideas became important in other parts of Europe (e.g., Russian) as well.

The ideology of the Enlightenment died in Europe at the beginning of the 19th century. This was also visible in the language of law. Germany is an illustrative example. It is true that in this country more and more words of foreign origin were eliminated from the legal language, partly due to the ideology of German nationalism. However, statutes were no longer written for ordinary citizens but, rather, for legal professionals. The great codification of the end of the 19th century, *Bürgerliches Gesetzbuch* (1900), still in force, is in appearance written in clear German (it includes very few words of foreign origin), but its terminology gives expression to a very complicated conceptual system. Furthermore, the legal rules in this codification are often formulated in an abstract way that makes them hard to understand.

After the Enlightenment, legal language seems to have become obscure everywhere (although in different ways). It is therefore understandable that a new concern for the quality of this language has grown up at the present time.

Legal Pragmatics

A discussion of the intersection of two crucial domains of human activity, language and law, requires an interdisciplinary approach, which is the underlying assumption of this article and one of the main tenets of pragmatics, the study of language in use. The language of the law is not only notorious for its lexical and syntactic complexity, which has given rise to criticism (e.g., Mellinkoff, 1963; Danet, 1980, 1985; Lakoff, 1990), but it also has certain pragmatic peculiarities. The present study on legal pragmatics will provide a pragmaticist's account of legal issues rather than a lawyer's view of the linguistic problems he or she faces. Since the direction of fit is from language to law and not from law to language, the assumption is that the aim of legal pragmatics is to construct an interface between the two domains by searching for pragmatic peculiarities in the language of the law. Thus, this article will investigate the instantiations of selected pragmatic concepts in the language of the law. The starting point of my analysis consists of a few observations on the topic made by others before.

1. The turn-taking system used in court is similar to that of other institutional settings (e.g., classrooms or chaired meetings) in that it is more rigid and less flexible than the one operating in everyday face-to-face conversation (Levinson, 1983: 301).
2. The institutionalized character of the court is reflected in formulaic, if slightly archaic and stilted language (Lakoff, 1990: 94).
3. According to Danet (1985: 276), legal discourse is concerned with "the nature, functions and consequences of language use in negotiation of social order." Despite its formulaic character, legal language employs a wide range of registers. It can represent various styles, ranging from frozen through formal and consultative to casual.
4. Verbal interaction in court exemplifies various questioning strategies, which lend themselves to a pragmalinguistic analysis, since "courtroom discourse is unilateral in that barristers enjoy a one-sided topic control of discourse" (Luchjenbroers, 1997: 477). This control is a sign of power, a socio-pragmatic concept discussed in the section 'Power vs. Solidarity' below.
5. Kurzon (1995) emphasized the role of silence in trial proceedings, and his more recent analysis (Kurzon, 2001) addressed the politeness of the judges. He claims that in formal language politeness may be

Thus, this article will investigate the instantiations of selected pragmatic concepts in the language of the law. The starting point of my analysis consists of a few observations on the topic made by others before.

1. The turn-taking system used in court is similar to that of other institutional settings (e.g., classrooms or chaired meetings) in that it is more rigid and less flexible than the one operating in everyday face-to-face conversation (Levinson, 1983: 301).
2. The institutionalized character of the court is reflected in formulaic, if slightly archaic and stilted language (Lakoff, 1990: 94).
3. According to Danet (1985: 276), legal discourse is concerned with "the nature, functions and consequences of language use in negotiation of social order." Despite its formulaic character, legal language employs a wide range of registers. It can represent various styles, ranging from frozen through formal and consultative to casual.
4. Verbal interaction in court exemplifies various questioning strategies, which lend themselves to a pragmalinguistic analysis, since "courtroom discourse is unilateral in that barristers enjoy a one-sided topic control of discourse" (Luchjenbroers, 1997: 477). This control is a sign of power, a socio-pragmatic concept discussed in the section 'Power vs. Solidarity' below.
5. Kurzon (1995) emphasized the role of silence in trial proceedings, and his more recent analysis (Kurzon, 2001) addressed the politeness of the judges. He claims that in formal language politeness may be

taken for granted and is therefore automatically present (it may in fact be presupposed).

Pragmatic Concepts in the Language of the Law

The main issue addressed here is the extent to which the language of the law lends itself to a pragmatic analysis, e.g., whether typical pragmatic notions can be found in this type of discourse. My hypothesis is that the language of the law shares most of the pragmatic properties of colloquial language. These are presupposition, deixis, implicature, speech acts, and power vs. solidarity.

Presupposition

The notion comes in different guises, such as: semantic, pragmatic, and lexical presupposition, but the most widely recognized distinction runs along the semantics-pragmatics line. Thus, semantic presupposition is a relation between two propositions, such that the presupposing proposition can be denied, whereas the presupposed one is immune to negation, i.e., it is always true. Among the so-called presupposition triggers are a variety of lexical items and syntactic constructions, e.g., Levinson (1983: 181ff) lists more than 30 such items. Take factive verbs like 'regret,' which presuppose the truth of their complements, e.g., in

(1) I (don't) regret that it's raining.

Here the truth of the complement sentence (i.e., that it is raining) cannot be denied, regardless of whether the verb in the main clause is negated or not. In contrast, pragmatic presupposition is a relation between two utterances whose truth/factuality is taken for granted in a given context due to the mutual knowledge of the speaker and the addressee(s). For instance, if I ask a secretary in my department 'Is the professor in?' the question would normally presuppose that there is only one professor in our immediate context, i.e., an instance of existential presupposition related to definite descriptions. However, in this case, both I and the secretary know that only one of the many professors in the department, viz. the boss, is referred to with the definite NP 'the professor,' rather than with 'Prof. Brown.'

As can be expected, questions with presuppositions permeate interrogations. Recall the proverbial:

(2) When are you going to stop beating your wife?

Commenting on such questions, Shuy (1998: 15) showed that they are particularly useful in the case of suspects whose guilt is uncertain. It turns out that questions with presuppositions intimidate the suspects who might think that the interrogators already know the facts that they do not.

In her analysis of the role of questions in Supreme Court trials, Luchjenbroers (1997: 482), following Danet (1980: 521ff), defined questions in terms of the degree of factuality of the potential answers, ranging from open-ended questions of 'high' fact value, through *wh*-questions, to restrictive 'yes/no' questions of 'low' fact value. Predictably, the counsel have least control over witness replies with the open-ended questions and maximal control with 'yes/no' questions. The latter are also called leading questions, where the interrogators provide the facts of a testimony and the witnesses either confirm or deny them. The counsel have control over the witness, since they do not only know the answer that they expect to hear, but also gear their questions accordingly. Thus, the answer to the counsel's leading question is presupposed as in the following examples of the most frequent forms which leading questions can take: declaratives, accusatory 'yes/no' questions, and alternative questions, cf. (3a), (3b), and (3c), respectively (notice the use of 'some' which, in contradistinction to 'any,' obviously presupposes the truth of the utterance):

(3a) You had some alcohol?
(3b) Did you have some alcohol?
(3c) Did you or didn't you have some alcohol?

(Luchjenbroers, 1997: 482).

Deixis

Another pragmatic concept of relevance here is deixis, which can be defined as the expression of spatiotemporal relations in language by means of 'indexicals' (pronouns and adverbs that indicate three transient notions: the participant roles, the place, and the time of the utterance, labeled person, place, time deixis, respectively), as in the classical example:

(4) I am here now.

This pragmatic spatiotemporal domain is relevant to an analysis of legal language, especially to court trial discourse, because there consecutive instances of deictic anchoring reflect the spatiotemporal relations between the actual event, its spoken testimony by the witness/defendant, its written records, and possibly its later reception by potential readers.

Since one of the purposes of a court examination is to determine the identity of various persons involved in a case, and the exact location and time of the event, all three major deictic categories are realized in what is called "factuality of persons, place and time,"

(Kryk-Kastovsky, 2002: 254ff). The category of person is grammaticalized in natural language by means of personal pronouns 'I,' 'you,' 'he/she' referring to the speaker, the addressee, and the third party, respectively. Consequently, personal pronouns used in court trial discourse should reflect the interpersonal relationships between different participants of the trial. Stygall (1994: 180) presented an insightful proposal that personal pronouns should be redistributed in two categories, placing the referent either in the trial world or in the abstract world of the legal universe. Thus, 'you' is ambiguous between two uses: it is deictic when it refers to the addressee(s) and nondeictic in its generic use. Singular pronouns like 'I,' 'he,' 'she' are obviously deictic, whereas 'it' can either be deictic (when it points to an entity), or nondeictic, i.e., when used as dummy subject. On the one hand, this observation contradicts the traditional view that while 'I' and 'you' are unambiguous in everyday discourse, the third person ('he'/'she'/'it')stands for the entities outside the discourse situation, and thus is often called 'a nonperson.' On the other hand, Stygall's stand correctly reflects one of the possible approaches to court trial discourse, i.e., that its structure consists of textual layers. In his study of old court trial records, Koch suggested three textual layers in which the dialogue going on in court can be embedded: legal framework of questioning, report of a statement, and a dialogue rendered as a quotation (Koch, 1999: 406ff).

In addition to the major deictic categories, scholars have also distinguished discourse, emotional, and social deixis. These can be labeled 'marginal deictic uses,' since as opposed to person, place, and time deixis, they are not obligatory occurrences determined by the very nature of language, but are totally dependent on the speaker's choices. Thus, discourse deixis points to a (proceeding or following) portion of the text/discourse, emotional deixis employs demonstratives to mark a personal attitude towards a given entity, and social deixis concerns the use of forms of address as markers of social distance, cf. (5a), (5b), and (5c), respectively (court trial transcripts from Shuy, 1998, emphasis mine):

(5a) Q: What stuff did you tell him that's true?
A: That I ain't did **that,** that I knew her for a long time.

(5b) A: Then when I got to school, **this** boy told me about what happened.

(5c) I have known **Ms. Lockhart** for about 2 years. Sometime I call her **Ms. Lillie**.
(Shuy, 1998: 164ff).

As we have seen, deixis is not only one of the major properties of spoken language (more than 90% of human utterances contain deictics), but for obvious reasons, it is even more pervasive in the language of the law.

Implicature

The Gricean idea of 'what is meant but not said' is undeniably relevant to the language of the law, where actual meanings have to be inferred from examinations, witness depositions, and other forms of judicial discourse. As Mey (1993: 99) stated, implicature is a regularity that cannot be captured in a simple syntactic or semantic rule, but by some conversational principle. One of the best-known examples of implicature comes from Levinson (1983: 97):

(6) A: Can you tell me the time?
B: Well, the milkman has come.

where A has to infer the answer (e.g., that the milkman always comes around 6 A.M., hence the time has to be about 6 A.M.).

In the context of a court trial the process of inferencing and the resulting notion of implicature might constitute useful tools both for the interrogators in asking questions and for the interrogated in providing or evading answers. Atkinson and Drew (1979) analyzed court trial discourse in conversational-analytic terms and have shown that, in contradistinction to conversation, which is more loosely organized (the turns are not prelocated), court examination involves question-and-answer sequences. Since the turns in court trial discourse are prelocated in one direction only (i.e., from the interrogators to the interrogated), any pauses in the examination of witnesses or defendants have an inferentially implicative character, i.e., after the witnesses and defendants provide their answers, the next turn reverts to counsel who self-select. Inferences also work on a more elusive, psychological side of the court trial discourse, since any utterance can be a basis for moral inferences made about the speaker by the hearer(s) (Atkinson and Drew, 1979: 68). Compare these observations to the role of perlocutions in everyday discourse as opposed to the perlocutions that occur in court trials and often carry moral and social obligations (Kryk-Kastovsky, 2002: 236ff).

Inferencing can also be employed to discover what Harris (1994, emphasis original) called ideological propositions in courtroom interaction, such as:

(7) This court is a **reasonable** court – trying to do **justice** to both sides in some disputes?

As Harris (1994: 161ff) rightly pointed out, the concepts of a court based on reason and exercising justice are ideological assumptions that underlie the judicial system by definition and are therefore often

quoted by public figures as the basic principles securing the credibility of the legal system and political democracy in general. Therefore, by challenging the justness of the court, the statement starts an ideological dispute and thus implicates an oppositional view of reality. Finally, as demonstrated by Shuy (2004: 11ff), the counsel can use inferencing analysis (which involves the working out of implicatures) in order to solve ambiguities occurring in depositions or recorded data.

Speech Acts

Speech acts are utterances whereby by saying something the speaker performs certain acts, which are called performatives, as opposed to constatives, i.e., mere statements. The distinction was introduced by Austin (1962) and elaborated on by Searle (1969), who distinguished between five classes of performative utterances: representatives, directives, commissives, expressives, and declarations. In his later work, Searle (1975) emphasized the crucial role that performatives (especially declarations) play in legal language, whereas Danet gives priority to directives since "Within the facultative-regulative functions of law they are the most prominent in legislation that imposes obligations," (Danet, 1980: 458).

Speech acts are among the pragmatic concepts that most frequently occur in legal language, since according to Hencher, "[s]peech act theory and the law are made of much the same stuff. Pragmatic concepts such as authority, verifiability, and obligation are basic to both" (Hencher, 1980: 254). The crucial role of speech acts in the language of the law has also been shown in Jori (1994), Maley (1994), and Stygall (1994). Legal discourse is, by definition, permeated with performatives used by the speakers to perform legal acts. This evidence has been demonstrated by Danet, who claims that representatives, which commit the speaker to the truth of a proposition, can express a strong or a weak commitment, e.g., actions of testifying or swearing vs. asserting or claiming, respectively. Since according to Austin law is a set of commands, even more important to the legal language are directives, future-oriented speech acts intended to change the current state of affairs by making someone to perform some action, e.g., subpoenas, jury instructions, or appeals. Commissives, as the name suggests, commit the speaker to a future action, which includes any kind of contract, whether a business contract, a marriage, or a will. Expressives are supposed to cover cases of the convicted persons, asked before the sentence is announced whether they have anything (personal) to say. This moment is when they have the last opportunity to apologize, excuse themselves, and deplore their crime. Finally, declarations produce a fit between the words and the world, a change that comes about because of the speaker's utterance, as in the classic

(8) I declare the meeting closed. (Danet, 1980: 458ff)

It must be noted, however, that the position of formulaic expressions in legal language goes far beyond single speech acts, like swearing in a witness, requesting information, or warning the suspect of his/her constitutional rights, as in the case of Miranda Rights:

1. The suspect has a right to remain silent and he need not answer any questions;
2. If he does answer questions, his answers can be used as evidence against him.
3. He has a right to consult with a lawyer and if he cannot afford hiring a lawyer, one will be provided for him without cost. (Shuy, 1998: 52)

These speech acts are also part of a larger speech event. Such an event can be analyzed not only in linguistic terms, but also in terms of nonverbal context (e.g., spatial positioning and alignment in the courtroom) that can provide information concerning the social organization of discourse (Philips, 1986). Moreover, the physical characteristics of the courtroom emanate the atmosphere of power exercised by the interrogators (Lakoff, 1990: 91ff; Maley, 1994: 32ff). And it is the notion of power that this article will now address.

Power vs. Solidarity

Power in the Courtroom The distinction between power vs. solidarity introduced by Brown and Gilman (1960), was later been taken up by various theories of politeness, especially by Brown and Levinson (1987). The interplay between power and solidarity is apparent in the context of the courtroom where the interrogators exercise their power on the interrogated. The asymmetrical relation was particularly acute in the past, e.g., in early modern England, when judges could use their power by verbally abusing the witnesses and the defendants. For instance, the infamous Judge Jeffreys addressed the interrogated with invectives like 'blockhead' or 'vile wretch' (Kryk-Kastovsky, 2002: 253). The change in the politeness system to the effect that both social inferiors and social superiors receive the polite forms of address has also had repercussions in the judicial jargon, so that nowadays the distance between the interrogators and the interrogated is much more subtle. While the obnoxious behavior of judges is no longer possible nowadays, some more innocuous ways of indicating

the distance can be detected. On the extralinguistic side, it is the spatial organization of the courtroom that creates distance between the interrogators and the interrogated both due to the superior position of the judge (Lakoff, 1990: 87ff) and the role of the counsel who "reduce the witness to a function of a puppet" (Luchjenbroers, 1997: 480). On the linguistic side, the distinction between power and solidarity can be exemplified by the use of the appropriate forms of address and bythe presence vs. absence of the legal jargon in the speech of the insiders and outsiders of the courtroom, respectively. Moreover, the power contrast can also be detected in the verbal behavior of men and women. As noticed by O'Barr (1982), who follows Lakoff (1975), women's speech is much more tentative and less convincing due to the use of hedges, (super)polite forms, tag questions, speaking in italics, empty adjectives, hypercorrect grammar and pronunciation, lack of a sense of humor, etc. On the basis of these characteristics, O'Barr makes the distinction between powerful vs. powerless speech and shows that although women use powerless speech more often than men, the two categories are not necessarily to be assigned to the two sexes, but rather they reflect the social position of the speaker (the less powerful the speaker's social position, the less powerful his/her language). The transcripts quoted by the author convincingly demonstrate that powerful language is much more effective in courtroom discourse than powerless language. Consider the following quotation from O'Barr (1982: 65ff), where the emphasized words and expressions are clear instances of powerless language (emphasis mine):

(9) Q: State whether or not, Mrs. A, you were acquainted with or knew the late Mrs. X.
A: **Quite well.**
Q: What was the nature of your acquaintance with her?
A: **Well**, we were, **uh, very** close friends. **Uh**, she was even **sort of** like a mother to me.

As stated above, one of the manifestations of power and solidarity are forms of address, and this is what our discussion will now turn to.

Forms of Address Legal language as a conservative register has preserved many of the old address forms. Even in countries like the United States, where addressing others with first names is quite common, the language used in court is characterized by a high level of formality. Thus, the judge can be addressed as 'Your Honor,' 'The court,' or much less formally as 'Judge Smith' (although here some restrictions apply). In addressing the judge directly, the traditional formula 'May it please the court' is used. Lawyers are addressed and referred to as 'Counsel,' and members of the jury are addressed with the names of their social roles, e.g., 'Juror Number One' (depending on the assigned seat). Interestingly, the same formal register holds true for the interrogated, who are referred to as 'the witness' and 'the defendant' (Lakoff, 1990: 93). Although analogous situations hold in other languages with regard to referring to the participants of a court trial discourse, crosslinguistic variation applies to the ways a suspect/defendant/convict is referred to in the media. While in English, he is invariably referred to as 'Mr Brown,' in German the first and second name, without the honorific 'Herr,' are employed ('Harald Braun'), and in Polish merely the second name, again without the honorific, is used ('Kowalski'). It might be insightful to look into the (historical and sociocultural) reasons why loss of honorifics is the case in the two languages that have much more elaborate address systems than English. After all, German and Polish employ the T/V distinction (grammaticalized as *du/Sie* and *ty/Pan-i*, respectively), so that the use of honorifics is subject to strict sociopragmatic principles.

The Structure of Courtroom Discourse

In the following section, this article will examine to what extent courtroom discourse can be considered an approximation to everyday speech. As shown above, legal language contains all the major (socio)-pragmatic categories present in everyday communication. Therefore, it might be reasonable to assume that the parallel also holds on the discourse-analytic level; in other words, that the organization of courtroom discourse does not markedly differ from everyday discourse.

Guidelines for Courtroom Discourse Participants

Intuitively, one of the major characteristics of court trial discourse should be its effectiveness in achieving discoursal goals. Such effective courtroom tactics can be found in trial practice manuals addressed to what O'Barr (1982) calls "legal tacticians." Just to quote a few selected speech characteristics recommended by the authors of such manuals:

1. Overly talkative witnesses are not persuasive.
2. Narrative answers are more persuasive than fragmented ones.
3. Exaggeration weakens a witness's testimony, etc.

As can be expected, lawyers are also given advice as to effective verbal behavior (O'Barr, 1982: 32ff):

1. Make effective use of variations in questions format to get the most favorable responses for your

client. Interestingly, O'Barr notes that lawyers are often warned against asking questions to which they do not know the answers (i.e., they should resort to leading questions, cf. the section Presupposition above).

2. Another recommendation pertinent to this analysis is to vary the styles of questioning depending on the different kinds of witnesses (men vs. women, the elderly, children, etc.), a differentiation one might dub sociopragmatic, cf. the remarks on powerful vs. powerless speech in the section Power vs. Solidarity above.
3. Finally, a piece of advice that reminds a (text) linguist of a cohesion device, i.e., repetition is useful for emphasis, but it should be used with care.

With these guidelines in mind, let us now have a look at the main differences between two types of discourse of interest here, court examination and everyday conversation.

Court Examination vs. Conversation

At a first glance, court trial discourse looks analogous to any other discourse. However, Atkinson and Drew (1979) warn the non-initiates against hasty generalizations by showing to what extent court examinations can be compared to everyday interaction. First, if we consider the structural characteristics of conversation outlined by Sacks *et al.* (1974), i.e., turn-taking, turn allocation, transition-relevance places (TRPs), repairs, etc., predictably, everyday conversation is much more loosely organized than court trial discourse, so that in a conversation the turns are (relatively) spontaneous and the number of participants may vary. Second, while in court the distribution of power relations is obvious, in everyday conversation any power relations between its participants are not demonstrated overtly due to the different social setting of this type of discourse, which would imply that the Politeness Principle is observed. Third, although questions and answers often occur in a conversation, they are not a norm, whereas the verbal exchange in a court examination consists solely of question-and-answer pairs (Atkinson and Drew, 1979: 61ff). Moreover, in court examinations turn order is fixed and so is the type of turn contributed by each speaker. As Stygall rightly pointed out, turns and TRPs are controlled by the interrogators, whereas repairs and self-repairs, instigated by the questioning process, come from the interrogated (1994: 117ff). Indeed, the relation between the representatives of the two social roles is asymmetric in that only the interrogators have the right to ask questions, and the turns of the interrogated necessarily constitute (preferably adequate) answers to these questions. In other words, the turns in court examination, unlike in a conversation, are pre-allocated, or to use the terminology of Sacks *et al.* (1974), only one party (the interrogators) self-selects.

A unique property that differentiates court trial discourse from everyday conversation is what is called 'legal metacomments' (Kryk-Kastovsky, 2002: 248ff). These comprise the interrogators' comments on whatever is going on in court and are an instantiation of the metacommunicative function of language. Legal metacomments easily lend themselves to a pragmatic analysis due to their peculiar characteristics, in a way comparable to discourse deixis in everyday conversation. Thus, legal metacomments either refer (anaphorically) to a portion of previous discourse, or (exophorically) to a situation outside the actual discourse situation, cf. (10) and (11), respectively. In (10), the metalinguistic use of the verb 'say' takes the utterance outside the actual situation-of-utterance and gives it a special discourse function (i.e., that of a leading question), whereas in (11) the question is commented on by the judge as leading the witness, i.e., its discourse function is also changed from a simple 'yes/no' question to a leading question:

(10) So you say you actually ran away on Friday night? (Johnson, 2004: 105)

(11) Q: All right. Now the car the man was driving, was it a brown, a brown 1972 Chevrolet Nova?
OPPOSITION LAWYER: Objection.
JUDGE: Sustained, leading the witness. (O'Barr, 1982: 142)

The Language of the Law – At the Crossroads of Sociopragmatics, Discourse Analysis, and Intercultural Communication

It follows from the discussion above that (legal) pragmatics does not suffice to explain the intricate interface of language and the law. One of the reasons is that the relation between the two disciplines cannot be reduced to a simple combination of a few pragmatic concepts that occur in courtroom discourse; it calls for a multidisciplinary approach. Apart from pragmatics proper, a broader approach is necessary. First, the relations between the participants of court trial discourse call for a sociopragmatic explanation in terms of power and solidarity and the role which these concepts play in polite behavior, in the use of forms of address, etc. Second, an analysis of the structure and organization of courtroom discourse should be conducted within the conversation-analytic

and/or discourse-analytic frameworks to provide a comparison between the verbal exchanges in the courtroom and everyday conversation. Finally, on a more global level, a crosslinguistic and intercultural investigation might be in order to juxtapose the intricacies of the use of legal language in various cultural-linguistic communities. Not only would such as investigation reveal the differences between the Anglo-Saxon and European judicial systems, but also the various organizational peculiarities that result from these differences. Since in Great Britain and the United States the trial procedure is adversarial, whereas in most other countries it is inquisitorial, the following consequences ensue. In adversarial systems, the jury (consisting of lay persons) plays a crucial role in the trial proceedings. While the judge presides, the jury is presented the evidence from both the prosecution and the defense, and decides which side sounds more convincing. The inquisitorial trial procedure is much more rigid in that professional judges listen to the evidence presented by a state-appointed attorney and deliver a verdict. This style puts the defendant at a disadvantage, especially if his/her side is not fully represented. The markedly different roles played by professionals and laymen in both legal systems have serious repercussions for the entire organization of the trial procedures and the chances of the defendants (Lakoff, 1990: 86). Finally, it might also be useful to look at the organization of court trial discourse in countries outside Europe and North America and study different legal traditions, e.g., the court trial procedures in China deeply rooted in Chinese culture based on Confucianism, cf. e.g. Gao (2003).

Introduction

As the principal agents of social control, the police are the most visible, accessible, and available representatives of the criminal law (Black, 1980). They, by virtue of their uniform, badge, gun, and other occupational accouterments display palpable coercive power (Niederhoffer, 1967). And as the primary gatekeepers of the justice system, they determine which cases – persons – enter the criminal justice system; to that end they exercise a considerable amount of discretion (Black, 2005). Prior scholars have maintained that the decision to apply the law in police–citizen encounters is axiomatically linked to the demeanor of the citizens involved (Lundmann, 1994). In other words, the likelihood of receiving tickets, being arrested, and having other official – and unofficial – sanctions applied has been demonstrated to be contingent upon citizens' attitude and comportment toward the police.

Police–citizen encounters are, by definition, asymmetrical since the police possess the brute capacity to threaten, harm, and coerce the clients of their service into compliance; at the same time, the encounters are tinged with a veneer of sociality in that the bulk of police work involves a fundamentally interactive process. That is, the essence of police work entails explaining, requesting, directing, and counseling citizens, victims, witnesses, and suspects to get them to do something (Mastrofski *et al*., 2000). Yet, despite the communicative nature of police–citizen encounters, researchers have not been able to agree on the constitutive elements of disrespectful behavior; this highlights one of the major limitations of existing police scholarship: there has yet to be a principled and rigorous empirical expatiation of the communicative – intersubjective – nature of police work.

How a police officer communicates with citizens and colleagues has been regarded as the paragon of police professionalism (Muir, 1977). In a very obvious way, language is the vehicle through which knowledge, intention, and meaning is transmitted; furthermore, that the police use language to persuade and dissuade citizens from certain courses of action points to its assumed, yet empirically unexplored, rhetorical function. From this standpoint, aside from the obvious capacity to exercise coercion, a theoretically warranted question it generates is how that awesome power is embodied in a much more mundane form of social action.

This article, rather than assuming *prima facie* the capacity of the police to threaten, hurt, and kill the very purveyors of that power, demonstrates how that awesome power is interactionally, structurally, and socially enacted, exercised, and contested in the semiotic details of police–citizen interactions. How is the interaction between the police and the public made meaningful during the interaction? How do the contours of police ideology, authority, and identity extend to the realm of communicative interaction, and how might they be enacted and sustained during such moments? Does the coercive power of the police manifest itself even in something as prosaic as talk and other signaling systems? This article examines how the encounter between the police and the public is semiotically organized.

Instantiating the Interaction: The Semiotic Summons

As other police scholars have already noted, the work that the police do begins in two ways: citizen-initiated or police-initiated (Wilson, 1968). The talk between the police and citizens also begins in a similar way: either citizens contact the police or the police initiate their contacts with the citizens. Citizens contact the police to request help for troubles and problems they witness or experience (Whalen and Zimmerman, 1990; Zimmerman, 1992), and they do so through emergency call numbers, such as 911 in the United States. The request for assistance is then symbolically encoded into organizationally relevant codes and assigned to the police (Manning, 1988).

When the talk between the police and citizens is police-initiated, more salient differences – and

Introduction

As the principal agents of social control, the police are the most visible, accessible, and available representatives of the criminal law (Black, 1980). They, by virtue of their uniform, badge, gun, and other occupational accouterments display palpable coercive power (Niederhoffer, 1967). And as the primary gatekeepers of the justice system, they determine which cases – persons – enter the criminal justice system; to that end they exercise a considerable amount of discretion (Black, 2005). Prior scholars have maintained that the decision to apply the law in police–citizen encounters is axiomatically linked to the demeanor of the citizens involved (Lundmann, 1994). In other words, the likelihood of receiving tickets, being arrested, and having other official – and unofficial – sanctions applied has been demonstrated to be contingent upon citizens' attitude and comportment toward the police.

Police–citizen encounters are, by definition, asymmetrical since the police possess the brute capacity to threaten, harm, and coerce the clients of their service into compliance; at the same time, the encounters are tinged with a veneer of sociality in that the bulk of police work involves a fundamentally interactive process. That is, the essence of police work entails explaining, requesting, directing, and counseling citizens, victims, witnesses, and suspects to get them to do something (Mastrofski *et al*., 2000). Yet, despite the communicative nature of police–citizen encounters, researchers have not been able to agree on the constitutive elements of disrespectful behavior; this highlights one of the major limitations of existing police scholarship: there has yet to be a principled and rigorous empirical expatiation of the communicative – intersubjective – nature of police work.

How a police officer communicates with citizens and colleagues has been regarded as the paragon of police professionalism (Muir, 1977). In a very obvious way, language is the vehicle through which knowledge, intention, and meaning is transmitted; furthermore, that the police use language to persuade and dissuade citizens from certain courses of action points to its assumed, yet empirically unexplored, rhetorical function. From this standpoint, aside from the obvious capacity to exercise coercion, a theoretically warranted question it generates is how that awesome power is embodied in a much more mundane form of social action.

This article, rather than assuming *prima facie* the capacity of the police to threaten, hurt, and kill the very purveyors of that power, demonstrates how that awesome power is interactionally, structurally, and socially enacted, exercised, and contested in the semiotic details of police–citizen interactions. How is the interaction between the police and the public made meaningful during the interaction? How do the contours of police ideology, authority, and identity extend to the realm of communicative interaction, and how might they be enacted and sustained during such moments? Does the coercive power of the police manifest itself even in something as prosaic as talk and other signaling systems? This article examines how the encounter between the police and the public is semiotically organized.

Instantiating the Interaction: The Semiotic Summons

As other police scholars have already noted, the work that the police do begins in two ways: citizen-initiated or police-initiated (Wilson, 1968). The talk between the police and citizens also begins in a similar way: either citizens contact the police or the police initiate their contacts with the citizens. Citizens contact the police to request help for troubles and problems they witness or experience (Whalen and Zimmerman, 1990; Zimmerman, 1992), and they do so through emergency call numbers, such as 911 in the United States. The request for assistance is then symbolically encoded into organizationally relevant codes and assigned to the police (Manning, 1988).

When the talk between the police and citizens is police-initiated, more salient differences – and

controversies – emerge. Self-generated police activity such as suspicious person stops, traffic stops, and vehicle searches intrude into the lives of citizens: it hinders free movement and contradicts principles of democracy (Skolnick and Fyfe, 1993). Moreover, these types of activities usually involve members of the minority; hence, they are fraught with controversy (Radelet, 1977; Spitzer, 1999). A good example of a police initiated encounter is the traffic or vehicle stop – for driving through a red light, running a stop sign, speeding, driving with broken taillight etc.

In traffic stops, the police initiate the encounter, thus hailing another to interact, by activating their sirens, horns, and flashing lights. Those nonverbal signs constitute a visual and aural – semiotic – summons. To appreciate the pragmatic force of such a summons, it must be noted that police–citizen encounters are different from other mundane interactions in a rudimentary way. First, police–citizen encounters are bureaucratic and institutional occasions for talk; hence, different from ordinary conversations that unfold over a dinner table or over coffee in that the structures of talk are preallocated as a function of institutionality (Atkinson and Drew, 1979; Drew and Heritage, 1992). Yet, despite this difference, institutional encounters draw their communicative intelligibility from a mundanely recurring and locally organized site of sociality (Schegloff, 1999).

Research has shown that in one of the most banal and recurring sites of social interaction – opening sequences in 500 ordinary telephone calls – talk is interactionally ordered and sequentially organized (Schegloff, 1968). That is, telephone openings are marked by several core sequences: the ringing of the telephone constitutes a summons, beckoning the called party to answer, thus establishing a means of communication, and forming the summons/answer sequence. Next, the identification/recognition sequence is accomplished through the greeting sequence. And it is after the how-are-you sequence that the reason for the call is introduced. That burden – introducing the first topic – canonically belongs to the caller (Schegloff, 1968).

According to Whalen and Zimmerman (1987), the opening sequences in emergency call centers – whose business is related to the context of law enforcement – are structurally and sequentially different from openings in ordinary conversations and other institutional discourses. Calls to emergency services, such as fire, police, and paramedics, are socially organized into the following core components: (1) prebeginning, (2) opening/identification/acknowledgment sequence, (3) request, (4) interrogative series, (5) response, (6) close (Whalen and Zimmerman, 1987; Whalen *et al.*, 1988; Zimmerman, 1992).

Prebeginnings refer to the – unobservable – physical act of picking up a phone and dialing the other party's number (911), "thereby summoning another to interact" (Whalen and Zimmerman, 1987: 180). In such institutional contexts, the callers generally remain anonymous; consequently, the task of self-identification falls to the institution, and it is categorical. A key point of difference between openings in ordinary telephone conversations and emergency calls for assistance then involves the reduction of opening sequences: "Reduction plays an important role in achieving an institutionally constrained focus to the talk, for it routinely locates the first topic slot to the callers in their first turn, which is the second turn of the call" (Whalen and Zimmerman, 1987: 175). In ordinary talk, the caller or the called party may introduce the topic through preemptive moves; however, Whalen and Zimmerman (1987) and Zimmerman (1992) find that the callers' first turn is the environment where topics are initiated in calls to emergency centers.

Whalen and Zimmerman note that when citizens call emergency services it begins with a categorical identification by the dispatcher (e.g., Mid-City Emergency, nine-one-one emergency). Calls to emergency centers have been chosen as a point of departure because they are genealogically related to the law enforcement context of this paper (for other institutional discourses see Clayman and Heritage, 2002). First, the structural organization of institutional communication is derived from the structures found in ordinary talk; that is, institutional talk is modified and adapted from ordinary talk to meet the contextual and situational exigencies of talk at work (see Drew and Heritage, 1992). This difference is exemplified in calls to emergency centers; scholars such as Don Zimmerman, Marilyn Whalen, and Jack Whalen have demonstrated how calls to emergency centers are different from ordinary conversations (e.g., telephone calls); furthermore, their work parallels the research that semioticians have done on the police communication systems (Manning, 1988). The missing component of this body of research is what happens after the police are dispatched to a call, when they encounter the citizens – how do the police go about settling and managing their assignments?

The identities in calls to emergency centers are organized such that the call-taker (dispatcher) chooses identification-oriented recognition over recognition-oriented response to the telephone summons. When citizens call emergency services for exigent problems or pressing troubles they may have experienced or witnessed, the format of talk is constrained in such a way that the business of the

institution is built into the structure of the talk itself (i.e., institution speaks first). Thus, following the first sequence, citizens make a request for service (police, fire, paramedics), state the reason for the call (e.g., somebody just vandalized my car); or the request and categorical self-identification component of the call is collapsed into the opening first turn (e.g., nine-one-one, what is your emergency?). Just as callers to emergency centers initiate contact for assistance, the police, much like callers to emergency centers, initiate contact with motorists concerning a particular problematic relevancy – what the traffic stop is about.

If activation of sirens, flashing lights, and horns constitutes an identification-oriented summons – identifying the police *qua* police by virtue of their flashing lights – then the answering of that summons is the act of pulling over. Motorists, however, do not respond to the summons in equal ways; they do so in ways that shape their moral identity and the contours of the interaction. Let me provide some concrete examples from my research. Patrol officers who are assigned to traffic enforcement (i.e., speeding infractions) 'set up' their radars to catch the speeding drivers at streets where traffic offenses are known to occur with regularity. Once motorists are 'clocked' on the radar, the officer must start from inertia and frantically catch up to the speeding car before 'lighting em' up' (activating the sirens). And it is during this 'preinteraction' phase, between inertia and activation of sirens, and prior to any verbal contact, that motorists' demeanor and moral character – and outcome – are conveyed to the police.

For example, some motorists do not pull over right away. In fact, they make a series of turns at the closest intersection in an attempt to 'lose' the pursuing officer. Some succeed. Some motorists stop in the middle of the road, without pulling over to the shoulder, putting themselves, passing motorists, and the officer in danger. Some motorists speed up and attempt to run and instantiate a pursuit. Some motorists do not speed, but they do not pull over either. They lazily cruise to their homes, pull into the garage, park the car, and walk toward their backdoor, erroneously believing that they are immune from the summons book once inside the confines of their castle. Thus, through the different ways that motorists acknowledge and give recognition to the police as the police, prior to any conversational interaction, they convey to officers their attitude toward the police, as a 'governable' or an 'asshole' (van Maanen, 1978).

If this prebeginning determines, to a significant degree, the legal identities of motorists and colors the moral contours of the interaction, then a similar process also marks the lenient outcomes of these encounters. The research for this project was conducted in five different law enforcement agencies in two states, all with a distinct orientation toward the community, organizational values and norms, and size; and as part of the research, ride-alongs were supplemented with audio recordings of 50 traffic stops in those geographically different agencies. In the data, the police cited the motorists in 58% (29) of the cases, and released the drivers with a mere warning in 40% (20) of the cases; one driver was arrested. Some officers turned off their tape recorders when they decided they were going to release the speeding motorists (they thought the researcher would find them 'uninteresting'). Consequently, detailed notes had to be written at a later time. Consider the following field note of such an encounter:

> (Southern City Police Traffic Stop #16)
>
> As Officer H and I were sitting in the squad car, a white crown Victoria was clocked going over 50 miles per hour in a 30 miles per hour zone. The officer immediately turned on his lights and went after the car. As he began to close in on the speeding vehicle, the officer said to the researcher, "That looks a squad car doesn't it? I mean look at all the antennas it's got growing out of the car." When the speeding car came to a stop, the driver immediately got out; and as he was doing so, a sidearm and a (Southern) state police trooper's badge was visible on his belt. Moreover, it turned out that the state trooper was an acquaintance of the host officer. They briefly talked about family and work, and the state trooper mimicked an apologetic motorist in a sarcastic way: "I'm sorry for speeding officer." Then Officer H said good bye and let the speeding trooper go.

In this traffic stop, a city cop in a marked squad car pulls over a speeding, unmarked state police vehicle. Yet, despite the expansive authority of the state police over city police, the trooper obeys the summons to interact by pulling over. That is, the state trooper, by pulling over, acknowledges and gives recognition to the categorical and absolute authority of the city police as police, thus sustaining the legitimacy and authority of the police.

But notice that the seeds of clemency are recognized before the speeding motorist even completes the act of pulling over. Officer H recognizes the speeding car as a potential 'kinsman' in blue. ("That looks a squad car doesn't it? I mean look at all the antennas it's got growing out of the car.") Police officers do not, generally, as a matter of professional courtesy, ticket other police (this courtesy is extended to doctors, prosecutors, judges, and clergy). Thus, the speeding state trooper's act of obeisance to the local authority is mutually ratified and acknowledged as such in the semiotic moments of the traffic stop. Moreover, the trooper steps out of his car, and in the process, reveals

his sidearm and badge, thus signifying his identity as the police.

It turns out that the speeding motorist is the benefactor of leniency in two ways, as a kinsman in blue and a personal acquaintance. Even when a cop pulls over another cop, traffic stops begin with a prebeginning where the officer activates the squad's lights to initiate the interaction. In the excerpt above, the interaction that begins as an identification-oriented sequence is transformed into a recognition-oriented one after the host cop recognizes the law violator in a categorical (fellow cop) and social way (acquaintance). The point worth reiterating is that even other police officers follow the interactional order of traffic stops, and the accusatorial force of the semiotic summons, thus becoming collaborators in the productions of their legal and moral identities in the prebeginnings of the institutional encounter (Shon, 2005).

The semiotic nature of police–citizen encounters, and the summons, is further supported when the opening sequences of the conversations between the police and the public are examined. For instance, Chicago police officers are instructed in the training academy to pull the vehicle over, walk up to the vehicle, and initiate traffic stops with a self-introduction such as "Hi, how you doing tonight. My name is Officer X of the Chicago Police Department. May I see your driver's license and proof of insurance please?" Once motorists provide the officer with necessary documents, officers are taught to ask, "Do you know why I stopped you?" The rationale, according to the instructors at the training academy, is that this question "opens communication between citizens and the police." As one patrol officer related to me, "Some people have a good reason for breaking traffic laws." What is noteworthy is that police officers in actual stops or on mass mediated programs about police work (e.g., *COPS*) rarely make such formal and categorical self-introductions.

COPS is a reality television program about police work. The show employs no actors; the participants are all real police officers who go about responding to calls for service. And as the first of its kind to blend reality programming and policing, in a compressed format and distinct series of vignettes, it purports to provide viewers with an intimate peek into the mundane and fantastic aspects of routine police work.

The Institutionality of Presence and Absence

It is possible to attribute the absence of formal and categorical self-introductions in police work to the size of a department and its locale. However, rather than explaining its presence and absence exogenously, there is a sociosemiotic way to account for such a phenomenon. That is, the police rely on the visual and symbolic accouterments of the uniform and the patrol car to convey their institutional affiliation. In other words, they are oriented toward culturally normative recognitional identification rather than identification-oriented recognition. As one patrol officer snidely remarked to me, "What, they can't see the flashing lights and my badge and my gun and tell who I am? I'm the police." The semiotic summons initializes the encounter, which is then followed by the bureaucratic request to see a driver's license in the officer's first turn. Not all patrol officers, however, 'close' the introduction slot. This observation can be further strengthened from the following traffic stop data from *COPS*:

(*COPS* data: "You got an attitude")

3 PO1: Turn it off
4 D: Huh?
5 PO1: TURN IT OFF
6 Can I see yo hands ( ) who's car?
7 D: Mine
8 PO1: Step on out
9 Hands on the car
10 You have a license or ID?
11 D: Yea I got ID
12 PO1: Slide back back back of the car right here
13 D: (mumble) Hey uhh
14 PO2: Hey what's up? That's what up ah-ight? first of all you don't have
15 a driver's license so you're not supposed to be driving a car
16 that's the first thing. I don't care whether you bought the car or
17 not the law says for you to operate this car you have to
18 have a valid driver's license. Now you have an attitude
19 you got a taillight out

This episode of *COPS* takes place in Philadelphia. Two patrol officers make a traffic stop after witnessing a car driving at high speeds; in addition, the car does not have visible license plates. After they activate the sirens and pull the car over, both officers approach the car and open the encounter in line 3. There is a lot of action taking place in this encounter. It should be noted, however, that these Philadelphia officers, much like Chicago officers, do not make formal self-introductions. They do not say, "Good evening. My name is Officer X of Philadelphia Police Department. May I see your driver's license and registration please?" Contrast the way the big city traffic stop is opened with a police department in a much smaller city:

(Southern City Police Traffic Stop #9)
PO: Hello. Can I see your driver's license please?
Good evening ma'am, my name is officer X with the Southern City Police Department. The reason I'm stopping
you is you are doing 42 in a 30. Is there any medical emergency you're in a hurry for?
D: (shakes her head)

In this traffic stop the officer does begin the interaction in a way that is characteristic of bureaucratic institutions: he introduces himself (my name is officer X) and categorically identifies his institutional affiliation (with the Southern City Police Department). This officer from the Southern City Police Department was assigned to the Traffic Division: his entire shift was spent making traffic stops for speeding. Other beat officers during the author's ride-alongs did not open the encounter (self-identification) in this way, although some did. There may be other reasons why this particular officer begins the encounter the way he does (small city police, traffic specialist, politeness); but the key point is that it **is** markedly different from the ones shown thus far.

That is because the summons/answer sequence and the identification/recognition sequence found in ordinary talk are reduced to one in traffic stops. The absence of formal and categorical identification of an officer's institutional affiliation is the norm from which other deviations occur – formal identification slots have to opened from a number of structural possibilities. By virtue of their uniforms, squad cars with flashing lights, and other occupational accouterments, the task of verbal self-introduction and categorical identification are not necessary since they are semiotically conveyed. The semiotic summons already identifies the 'caller' as the police. Thus, in a traffic stop, the summons/answer sequence and identification/recognition sequence – first semiotic turn – are compressed into a visual and aural communicative sequence, thus further reducing the opening sequences noted in prior work.

Conclusion

Police–citizen encounters are asymmetrical in an obvious way: as representatives of the criminal law, the police are anointed by the state with the capacity to exercise coercive (lethal) force over citizens to bring about compliance to their directives. To that end, they are shrouded in symbolism, given the necessary tools, and project vestiges of brute power. It would be too presumptuous, however, to believe that the asymmetry between the police and the public rests solely on the possession of this awesome power. The police do have the authority to stop citizens and motorists, interrogate them, and impede their movements, but they also have the power to control the structural patterns of communication. As shown here, the police bring that symbolic and bureaucratic power to life by semiotically summoning citizens to interact.

In the summons/answer sequence Schegloff formulated, the failure to answer a summons incurs only a morally accountable sanction. That is, if someone or something (telephone ring) calls and beckons interaction in a social encounter, it can be refused at a moral expense. However, when the police summon citizens to interact and that summons is ignored, the accountability they face is not only moral but also legal. They can be sternly commanded to do so; the police can physically grab citizens and force them to interact, and should they physically resist, the police can use pain compliance holds and strikes to make them interact. As Skolnick and Fyfe (1993) posit, however, the police need not use those types of methods; their mere presence – uniform, identity – sometimes, deters crime and forces citizens to change their behaviors.

This article has reviewed the summons/answer sequence in social and institutional encounters. A key finding in prior research is that ordinary summons sequences are reduced to meet the institutional and structural exigencies and constraints that bureaucracies face. It has shown how the summons sequence is further reduced and adapted to meet the situational relevancies of police work. That the police routinely rely on the uniform to convey their categorical, self-introductions alludes to another way their presence is semiotically marked (Shon, 1998). As shown here, the semiotic summons is the first step in giving that awesome power of the police a concrete face and an audible voice in the opening moments of traffic stops (Shon, 2003a, 2003b, 2003c).

There is tremendous diversity in the way motorists react to the wail of sirens and lights; and precisely because the presence of the police evokes a different range of responses, from hostility and fear to anger and rage, they have been conceptualized as 'Rorschach-in-uniform.' That motorists are being legally and semiotically summoned already carries the pragmatic sting of an accusation. That is to say, they are directly accused – with sirens, flashing lights, and horns – regarding some problematic relevancy, without a ratified knowledge of what that might be. Of course, this is not to say that motorists who are generally pulled over have no idea as to why they are being stopped: the manner in which the accusation is made is direct, but the accusation itself is indirect because it has yet to be announced, and ratified, in the opening moments.

Niederhoffer (1967: 1) observed long ago that the policeman is "clothed in a mantle of symbolism that stimulates fantasy and projection." The police are often baffled by the attitudes and behaviors citizens show them; they do not understand why citizens "stiffen with compulsive rage or anxiety at the sight of a patrol car"; for that matter, the uniform. For instance, in an informal gathering with police officers, one patrolman related how he had pulled over a motorist to warn her about low tire pressure, only to be greeted with severe indignation. Or as Baker (1985) notes, a highway patrolman offers a ride to a hitchhiker on Christmas Eve, only to be violently cursed at and attacked. Why would such seemingly friendly gestures engender such hostile responses?

It is tempting at this point to offer a reductionist and simple psychological explanation for motorists' apparently bizarre behavior. Thus, we could say that motorists and citizens who act out toward the police are not the models of mental health, that they are paranoid, crazy, antisocial, and have a deep-seated hatred of the police. We could even offer a historical explanation and claim that some motorists react belligerently toward the police because they have been systematically harassed and mistreated by the police. Or a contextual explanation and conjecture could be offered: the motorist is having a bad day, and is acting out toward the cop.

And it is tempting to stop here; but if the phenomenon is examined sociosemiotically, the act of being summoned, pulled over, covertly interrogated, and having the problem announced as part of the opening sequences of a traffic stop, then the analysis can be salvaged from inward-looking psychology by grounding analysis in observable, demonstrable, and empirical action that subjects engage in. The summons instantiates the bureaucratic power of the police through the wail of sirens and flashing lights, thus beckoning motorists to interact, but why motorists have been summoned to interact is not yet made relevant until a later turn. Thus, motorists are signaled as to the indeterminate nature of the problem without a ratified knowledge of the problematic relevancy: they are indirectly accused in a direct manner:

> "As you are driving down the highway, suddenly there are flashing lights in the rearview mirror and the whoop of a siren in your ears. A small dose of adrenaline surges into your blood stream. Your heart beats faster; your palms sweat. You feel guilty whether you've consciously done something or not" (Baker, 1985: 246).

Thus when motorists and citizens act belligerently to officers' apparently friendly and concerned overtures – telling citizens about a tire dangerously low on air; offering a ride to a hitchhiker on Christmas Eve – their reaction seems to point the finger at the squad car, flashing lights, officer, and his or her uniform. If a sociosemiotic explanation of traffic stops is adopted, a citizen's violent reaction is a reaction to the direct and blatant manner of accusation – the summons – not the uniform.

Legal Translation

S Šarčević, University of Rijeka, Rijeka, Croatia

© 2006 Elsevier Ltd. All rights reserved.

Although translations of legal documents are among the oldest and most important in the world, legal translation has long been neglected in translation studies. Thanks to recent impulses from comparative law and legal linguistics, a growing number of scholars and practitioners have been attracted to this interdisciplinary field, making legal translation one of the most vital areas of contemporary translation. In our age of globalization, translation plays a major role as a means of communication in national, supranational, and international law. The volume of legal translation in international organizations has increased significantly as a result of the modern trend of adopting treaties, conventions, and model laws in more than one language. International relations, international trade, and even international dispute resolution are more dependent on translation than ever before, as is the European Union, whose legislation is currently drafted in 20 official languages, all texts being equally authentic. At the national level, the number of plurilingual countries and regions that translate their national laws and administer justice in two or more official languages is on the rise, as is the number of countries that translate their legislation and other legal documents for information purposes.

Why Is Legal Translation Special?

In keeping with Sager's definition of specific-purpose texts, a legal text can be regarded as a communicative occurrence between specialists intended to serve a particular function (Sager *et al.*, 1980: 210) (*see* **Languages for Specific Purposes**). Although it is their function that distinguishes legal texts from other specific-purpose texts, linguists initially failed to recognize that sources of law, such as codes, statutes and regulations, and treaties and conventions are primarily prescriptive, as are contracts. Such texts are normative instruments that prescribe commands and prohibitions, grant permissions and powers, or create obligations and rights (Cornu, 2000: 268) (*see* **Definition/Rules in Legal Language**). Judicial decisions and documents used to carry on judicial and administrative proceedings, such as actions, pleadings, briefs, appeals, requests, etc., are primarily descriptive but usually contain prescriptive parts as well (*see* **Language of Legal Texts**). These two groups of texts constitute the main bulk of legal translation.

While lawyers agree that legal translation is a dual operation consisting of both "legal and interlingual transfer," in their opinion, the main operation is legal in nature (Sacco, 1990: 34). Legal texts require a special type of translation basically because the translations also produce legal effects and many have the force of law just like the original(s). Above all, skilled translators must possess considerable legal and language competence "to understand not only what the words mean and what a sentence means, but also what legal effect it is supposed to have, and how to achieve that legal effect in the other language" (Schroth, 1986: 56). Unlike other areas of specialized translation, the success of a legal translation is measured by its interpretation and application in

Legal Translation

S Šarčević, University of Rijeka, Rijeka, Croatia

© 2006 Elsevier Ltd. All rights reserved.

Although translations of legal documents are among the oldest and most important in the world, legal translation has long been neglected in translation studies. Thanks to recent impulses from comparative law and legal linguistics, a growing number of scholars and practitioners have been attracted to this interdisciplinary field, making legal translation one of the most vital areas of contemporary translation. In our age of globalization, translation plays a major role as a means of communication in national, supranational, and international law. The volume of legal translation in international organizations has increased significantly as a result of the modern trend of adopting treaties, conventions, and model laws in more than one language. International relations, international trade, and even international dispute resolution are more dependent on translation than ever before, as is the European Union, whose legislation is currently drafted in 20 official languages, all texts being equally authentic. At the national level, the number of plurilingual countries and regions that translate their national laws and administer justice in two or more official languages is on the rise, as is the number of countries that translate their legislation and other legal documents for information purposes.

Why Is Legal Translation Special?

In keeping with Sager's definition of specific-purpose texts, a legal text can be regarded as a communicative occurrence between specialists intended to serve a particular function (Sager *et al.*, 1980: 210) (*see* **Languages for Specific Purposes**). Although it is their function that distinguishes legal texts from other specific-purpose texts, linguists initially failed to recognize that sources of law, such as codes, statutes and regulations, and treaties and conventions are primarily prescriptive, as are contracts. Such texts are normative instruments that prescribe commands and prohibitions, grant permissions and powers, or create obligations and rights (Cornu, 2000: 268) (*see* **Definition/Rules in Legal Language**). Judicial decisions and documents used to carry on judicial and administrative proceedings, such as actions, pleadings, briefs, appeals, requests, etc., are primarily descriptive but usually contain prescriptive parts as well (*see* **Language of Legal Texts**). These two groups of texts constitute the main bulk of legal translation.

While lawyers agree that legal translation is a dual operation consisting of both "legal and interlingual transfer," in their opinion, the main operation is legal in nature (Sacco, 1990: 34). Legal texts require a special type of translation basically because the translations also produce legal effects and many have the force of law just like the original(s). Above all, skilled translators must possess considerable legal and language competence "to understand not only what the words mean and what a sentence means, but also what legal effect it is supposed to have, and how to achieve that legal effect in the other language" (Schroth, 1986: 56). Unlike other areas of specialized translation, the success of a legal translation is measured by its interpretation and application in

practice, especially by courts of law. Accuracy is thus essential, and as much attention must be paid to the content as to the intention and all possible interpretations and misinterpretations of the text. Translators must understand the source text but not interpret it in the legal sense. In particular, they must avoid value judgments, taking care to convey what *is said* in the source text, not what they believe it *ought to say*.

Contrary to texts of the exact sciences, legal texts do not have a single agreed meaning independent of local context but usually derive their meaning from a particular national legal system. This system is referred to as the *source* legal system, while the *target* legal system is the system to which the recipients of the target text belong. According to lawyers, the difficulty of a translation depends primarily on the degree to which the source and target legal systems are related and secondarily on the similarity of the source and target languages (cf. Berteloot, 1999: 103). In this sense, the difficulty of a translation increases when the legal systems belong to families with considerably different legal traditions and their languages are not related.

Sometimes it occurs that the source and target legal systems are identical, thus greatly facilitating the translation process, mainly because both texts derive their meaning from the same conceptual system. This is the case in plurilingual states with one legal system, such as Switzerland, Belgium, and Finland, as opposed to plurilingual states and regions with different legal systems or a mixed legal system (e.g., Canada, India, Sri Lanka, Israel, South Africa and recently China, in Hong Kong and Macau). Although European law is regarded as an independent legal system, 'Euroterms' and concepts are in a state of flux, causing confusion for translators who must distinguish between European and national institutions and concepts (Schübel-Pfister, 2004: 115). Despite increased efforts to unify law at the international level, the number of standardized concepts in international law is still small.

Conceptual Incongruity of Legal Systems

Lawyers often describe legal translation as a form of *transposition juridique* (Tallon, 1995: 342); by no means, however, is it a mere mechanical process of transcoding terminology from one legal system into another. On the contrary, the conceptual incongruity of legal systems poses the greatest challenge to legal translators, making it extremely difficult and sometimes impossible to find an adequate equivalent in the target legal system for a given term in the source legal system (*see* **Law and Language: Overview**). As in Hjelmslev's analysis of terminological incongruity in ordinary languages, it can be shown that the boundaries between the meanings of legal concepts are incongruent even in closely related legal systems, such as the continental civil law systems. For example, the concept of décision in French law corresponds with two, more specific concepts in German law (*Entscheidung* and *Beschluss*) and three in Dutch law (*Beschikking*, *Besluit*, *Beslissing*). Even etymological equivalents that constitute the common core of all legal systems, such as *dettes* and *debts* or *contrat* and *contract*, are not identical at the conceptual level. Moreover, within the same language, it occurs that the same term designates different concepts in different legal systems or, conversely, the same concept is designated by different terms in different jurisdictions. In addition, all legal systems contain a number of 'untranslatable' system-bound terms designating concepts peculiar to their own legal reality.

Not surprisingly, the majority of studies on legal translation deal with terminological problems. Early studies by lawyers focused on using methods of comparative law (especially the functional approach) to identify and compare the corresponding concepts of different legal systems. Hence, the terms designating such concepts are called functional equivalents (Šarčević, 1989: 278). Using functional equivalents is considered the "ideal method of translation" (Weston, 1991: 23). Frequently, however, they are only partially equivalent, or no functional equivalent exists in the target legal system, thus forcing translators to resort to linguistic means. As a result of recent interaction between lawyers and linguists, conceptual analysis is now being used to measure the degree of equivalence of the corresponding concepts of different legal systems; legal criteria have been established to determine the adequacy of functional equivalents; methods of lexical expansion and contraction are used to compensate for the incongruity of functional equivalents; and a catalogue of linguistic equivalents has been proposed to translate system-bound terms (literal equivalents, descriptive paraphrases, borrowings, naturalizations, and other neologisms).

Attempts to Provide a Systematic Approach to Legal Translation

The popularity of legal translation has been accompanied by a sharp increase in the number of scholarly publications by both lawyers and linguists, most of which focus on specific terminological issues, languages, legal systems, or text types. Only recently have there been attempts to establish general principles of legal translation. Aware of the inadequacies of general translation theories, specialists in legal

linguistics have attempted to analyze the phases of the translation process (Gémar, 1995) and propose a theoretical framework for legal translation based on both legal and linguistic criteria (Šarčević, 2000). Recent emphasis on the textual aspects of legal translation (syntactical, pragmatic, and stylistic) has shown that the quality of translations can be improved without compromising reliability.

For centuries literal translation was the only acceptable translation procedure for all legal texts, especially legislation (*see* **Approaches to Translation, Linguistic**). For the purpose of preserving the letter of the law, translators adhered to the principle of fidelity to the source text by reconstructing the form and substance of the original text as closely as possible. In fact, the dominance of literal translation was not seriously challenged until the 20th century when dissident translators began to demand equal language rights for lesser-used official languages. Accused of heresy by his critics, Rossel defended his liberal translation of the German text of the Swiss Civil Code into French (1907) by insisting that the francophone population of Switzerland had the right to have their code written in 'natural' French. In the 1960s, demands for equal treatment of the French language at the federal level in Canada triggered the so-called silent revolution in Quebec, emancipating translators by encouraging them to convey the sense of the original in a new text written in the genius of the target language. In the late 1970s, the Canadians went a step further by introducing new methods of bilingual drafting, the most common of which is co-drafting, a form of simultaneous text production that goes beyond translation.

While translators of Canadian federal legislation are encouraged to strive not so much for verbal and grammatical parallelism as for linguistic purity within the confines of legal equivalence (Beaupré, 1986: 179), the extent of the translator's freedom to produce a new text in the genius of the target language is controversial in other jurisdictions and for certain text types, mainly out of fear that the translator will scuttle the intent of the original. For example, translators of Swiss legislation are advised not to alter the length of sentences to avoid imposing their own interpretation. Similarly, translators of instruments of international law are instructed to give priority to formal concordance and to refrain from clarifying any ambiguities. Moreover, numerous legal instruments are institutional texts and as such are subject to a varying degree of standardization. Strict observance of standard form and formulae is required particularly in translations of documents of the European Union.

From the above, it follows that text type does play a role in determining translation strategy; however, there is no given strategy for translating a specific text type, such as legislation or judgments, even when the *skopos* (purpose) of the translation is the same (*see* **Functional Approaches to Translation: Skopos Theory**). Unlike other areas of translation, the *skopos* of a legal translation is often predetermined by its status, i.e., whether it is non-authoritative or authoritative. Whereas non-authoritative translations are intended for information purposes only, authoritative translations are legally binding instruments. In both cases, however, the selection of a translation strategy depends primarily on legal factors of the specific communication situation: which source and target legal systems are involved, how many, which drafting techniques and rules of interpretation are commonly used in those systems, etc.

Redefining the Goal of Legal Translation

The future of legal translation is bright, and there are valid arguments to elevate its status to an independent discipline in translation studies. A symbolic step in this direction could be taken by redefining the goal of legal translation. In the tradition of specific-purpose translation, it has long been accepted that the primary task of the legal translator is to achieve semantic equivalence (*see* **Translational Equivalence**). While this aim is in keeping with the presumption that a translation has the same meaning as the original(s), lawyers are the first to admit that legal translation is at best approximation, thus reducing the presumption of equal meaning to a fiction. Whereas it is not always possible to achieve semantic equivalence, translators are expected to produce texts that lead to the same legal effects in practice. Moreover, these are presumed to be the *intended* legal effects. Emphasizing the pragmatic aspects of legal translation (*see* **Legal Pragmatics**), it can be said that the translator's task is to put language into action to achieve the intended legal effects, i.e., to achieve legal equivalence. Although legal equivalence has far-reaching implications, it can essentially be regarded as a synthesis of content, intent, and legal effect, with the main emphasis on the latter.

In a receiver-oriented approach to legal translation, the test of legal equivalence is how the text is interpreted and applied by the courts. For example, the authoritative translations of a given instrument may be deemed legally equivalent if they are interpreted and applied uniformly by the courts. In this sense, the ultimate goal of legal translation is to produce a text that will promote the uniform interpretation and application of the single instrument, as it is called. Achieving this goal is not easy, however, it is hoped that greater interaction between lawyers and linguists

will lead to new and better methods of overcoming the legal and linguistic barriers of legal translation, making it a more effective means of communication in our global world.

Legal–Professional Language in Jury Trial

C Heffer, Nottingham Trent University, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

The study of legal–professional language in jury trial is concerned with how trial lawyers and judges use language in the context of legal cases tried by jury. While some code switching occurs between legal English and Standard English, brought on by frequent changes in topic and audience, it is often difficult to distinguish these linguistic varieties within the context of jury trial. Legal professionals often produce their own hybrid variety of language, a 'legal-lay discourse' (Heffer, 2005), which is neither truly legal in its lexis and syntax, nor typical of everyday

English. This discourse can partly be explained in terms of strategic tensions resulting from the need to persuade a lay jury to act in certain ways, but from within a highly constrained legal framework. Crucially, then, it is the complexity of the jury trial context which determines the complex nature of language use observable in court.

This entry will sketch out some of the key features of that complex context and consider how they influence the nature of the language used. It will also attempt to show how variation in context across legal jurisdictions can result in quite distinct linguistic preferences.

The Narrative Context and Opening Statements

At the heart of all cases tried by jury is a story of wrongdoing. That story needs to be presented by the prosecution or plaintiff to the jurors and will then be deconstructed by the defense, who might also present alternative stories. In addition to this 'natural' narrative context are lawyers' understandings of the process of jury decision-making. Lawyers have long understood the power of a good story, and this folk theory has recently found some support from psychological research into jury decision-making. Narrative coherence, for example, has been claimed to be more crucial to jurors than evidential weight (Bennett and Feldman, 1981), while a narrative form of presentation has been shown to enhance recall of story elements (Mandler, 1984). Both folk theory and science have fed into the advice of advocacy manuals (e.g., Evans, 1993), which now enthusiastically encourage narrative forms of presentation, and there is some empirical evidence that lawyers, particularly prosecution lawyers, do indeed follow narrative principles. In terms of the macro-organization of their cases, counsel will often try to ensure that their first witness is the one who can tell the story as completely as possible (e.g., a good eyewitness) and then subsequent witnesses will provide support for various elements of that story (e.g., forensic evidence). Counsel will often structure their examination-in-chief of the key 'storytelling' witnesses following a schema of natural narrative, such as 'setting-episode,' in which the scene is set and then the episode is recounted chronologically. Finally, lawyers are concerned not only with, as Jackson (1995) puts it, the 'story *in* the trial' (the story of wrongdoing) but also the 'story *of* the trial' (the events of the trial itself, including the impression made by witnesses and counsel).

The most crucial point of the trial for narrative presentation is the opening statement, for this will be the jury's initial exposure to the prosecution's story (and, in the U.S., that of the defense). Opening statements in most jurisdictions are supposed to be informative rather than persuasive, to provide an outline of the story and the legal issues rather than argue the case. They are potentially highly influential, though, since they construct a cognitive filter through which jurors will then view the subsequent evidence (Moore, 1989). The opening outline provides the core or master narrative while 'satellite narratives fill out, elaborate, and extend the narrative through the information gathered during the examination of witnesses' (Snedaker, 1991: 134).

The following is an abridged and anonymized version of the outline summary from a dangerous driving case, annotated to show how the structure conforms to a schema of natural narrative (Labov, 1972):

> *Orientation*
> [*When?*] At about 2:00 in the morning of November 16 last [*Who?*] four off-duty policemen [*What?*] were driving along in a white Toyota Corona [*Where?*] from the Ludley direction to the Bedley direction.
> *Complicating Action* (What happened then?)
> As they came up to [the Busby] bends, the car behind them came up close and (. . .) went out into the oncoming lane, over the double white lines and overtook.
> *Evaluation* (So what?)
> Those bends are a number of sharp and, in some cases, blind bends, and they have got double white lines in the middle of the road which, as you know, means you must not overtake there.
> *Resolution* (What finally happened?)
> The car continued (. . .) until it disappeared out of sight round the next blind left-hand bend.

Despite conforming to a natural narrative schema, there are a number of features in the complete narrative which mark it out as distinctive to trial narrative. In the first place, there is an apparent overspecification of orientational information. While the Orientation sentence above would be perfectly adequate for a newspaper narrative, here it is both preceded and followed with circumstantial detail such as the precise designation of the road, the names of all the passengers in the car, and a detailed description of the road. A second feature is the frequent blending of orientation and evaluation:

> As they were driving along – it is a single carriage road, a country lane; an 'A' road, but in the countryside with hedgerows either side, no streetlights – they become aware of a car coming up behind them fast.

Here the barrister is not so much providing descriptive background as suspending the narration to stress

the evaluative point he is making: that it was dangerous to overtake.

This suggests a third feature of trial narrative: a distinctive use of evaluation. In Labov's model of narrative, evaluation functions as both a primary and secondary structure. As a primary structure, Evaluation in trial narrative explicitly indicates the probative value of a piece of evidence, the 'Point' (Harris, 2001). This is indicated in several sections of the outline and then summed up in an evaluative Coda:

> The prosecution would say that is an obvious piece of dangerous driving.

As a secondary structure, evaluation appears throughout the narrative and tends to function in a more holistic fashion, gradually building up an impression that will influence the jury as much affectively as cognitively, as in the following lexical chain suggesting danger:

> no streetlights . . . fast . . . sharp . . . blind . . . close . . . in the middle of the night . . . obviously . . . cannot see

At this level of impression creation, the strategic choice of words can help prime the jury into viewing the events and participants in a given way, as Cotterill demonstrates in a detailed corpus linguistic analysis of lexical choices made in the opening statements of the O. J. Simpson criminal trial (2003: 68–83).

Narrative, then, is clearly central to case construction. Yet to a nonlegal observer, the evidential phase of a run-of-the-mill trial can appear quite unlike narrative. Although advocacy manuals insist that the aim in witness examination is for "the story to be told naturally, spontaneously and conversationally [thus] enhancing trust in the witness" (Stone, 1995: 95), in practice, extended witness narratives of any length are extremely rare. Much of the explanation for this discrepancy between the 'deep' narrative structure of cases and the superficial nonnarrativeness of trial genres can be found in the legal context of jury trial.

The Legal Context and Submissions

Language in jury trial is profoundly affected by both the law itself and by the mindset and customs of legal professionals. The substantive law both restricts the types of stories of wrongdoing that can be told in court and determines which elements of those narratives are legally relevant. The 'matters in issue' for legal professionals often differ from those considered relevant by lay participants, so that the narratives of lay litigants in small claims courts are often construed as legally inadequate (O'Barr and Conley, 1982). The narratives constructed by lawyers in court must fit the categories determined by the law and, in a criminal case, the legal elements of the indictment. This involves the lawyer controlling quite closely the direction a witness narrative takes and making sure that the 'materially relevant' evidential Points are being made. The narration is also constrained by rules of evidence. For example, lawyers must make sure the witness does not speculate or relate what others have said (hearsay).

There is also, though, a deeper level at which the legal context influences the language of legal professionals. As with most institutional discourse, lawyers and judges are heavily influenced by their professional training. Law students are trained to 'think like lawyers', and this is often different from lay ways of thinking (Mertz, 1996). Cases are viewed, for example, in terms of legal rules and principles and are effectively transformed from complex narratives of human vicissitudes to exemplars of decontextualized case categories.

Such legal reasoning is demonstrated in advocates' legal submissions to judges. In the English context, these are delivered orally in open court but in the absence of the jury. In the following extract from a submission, the barrister is attempting to persuade the judge of the legal correctness of dismissing one of the counts against the defendant, suggesting effectively that that particular legal story should not be told in court:

> To deal with the other matter, it is a question of dangerous driving in Count 1 of the indictment. Your Honor, I make a submission of no case in respect of that, and I do it for this reason: (. . .) one has, in dangerous driving cases, really two different types of circumstance in which dangerous driving can arise. One presents an objective test; one a subjective test. Of course, the offense is driving which falls far below the standard of the ordinary, prudent, and competent motorist. So, one has the 'far below' aspect. The second point is that the driving must be dangerous. Danger is defined as there being a danger that there would be (and the Statute uses the words 'would be') injury to the person, or substantial damage to property . . .

While researchers have tended to focus on advocates' attempts to influence the jury, counsel are equally concerned to convince the judge. More than 40% of English jury trials end in an acquittal ordered or directed by the judge, so this legal line of persuasion is potentially fruitful. It is also quite unlike that used on the jury. Here, the events of the trial are relevant only as an instantiation of a class of similar events which have been abstracted from time and place ('in dangerous driving cases'). Rather than a sequence of

causally related actions, the propositions are presented through existential processes in the timeless present ('it is,' 'one has'). Hypotheses are formulated and then tested ('one presents an objective test; one a subjective test'), and there is considerable reliance on definition ('Danger is defined as there being . . .') and on the precise wording of authoritative written texts ('the Statute uses the words "would be"'). In producing such discourse, the advocate is demonstrating his skills of legal argumentation to his professional superior, and although the submission in this case fails, he is praised by the judge for its construction – "very clearly made, if I may say so."

The Adversarial Context and Objection Sequences

While the deep structure of the trial might be determined by narrative and the law, the surface structure is more akin to classical debate. In a criminal trial, the prosecution sets forth its Proposition motion (that the defendant is guilty of certain crimes) in the Indictment. They then introduce the Argument For conviction in the Opening statement. This argument is developed through their own witnesses. Then the Defense presents the Argument Against conviction through its witnesses. Finally, Prosecution and Defense produce Perorations for and against the motion in their Closing Arguments. In addition to this overall adversarial structure, trial procedure allows for stories presented in court to be challenged at three other levels. First, the 'tellability' of the story itself can be challenged through legal submissions, as in the submission for no case above. Second, the satellite narratives of the witnesses can be challenged through **crossexamination**. Finally, opposing counsel can object at any point to the examiner's line of questioning.

While the highly adversarial nature of jury trial discourse is indisputable, the extent to which it is manifested before the jury varies considerably across jurisdictions. This is particularly evident in the handling of objections in U.S. vs. English courts. In U.S. courts, objections are both frequent and formulaic. Although admittedly an extreme case, the O. J. Simpson criminal trial contained more than 16 000 objection sequences (Cotterill, 2003: 95). Perhaps due to this frequency of use, a **sublanguage** has developed for performing objections, as illustrated in this example from the O. J. trial (2003: 95):

> Q: And Miss Mazzola was under the impression that you had left the Rockingham scene earlier than 5:20, wasn't she?
> Mr. Goldberg: Calls for speculation.
> The Court: Overruled.

Opposing counsel often initiate the objection with the legal performative 'Objection.' This is followed by an obligatory indication of the evidentiary cause for the objection, generally taken from a finite set of legal categories. Finally, the judge allows or disallows the objection using the terms 'Sustained' or 'Overruled.'

In contrast, objection sequences are quite rare in English jury trials. Judges can and do intervene directly to object to or redirect a line of questioning. Furthermore, objections are perceived by barristers to be disfavored both by judges (for interrupting the flow of the examination) and jurors (for concealing information from them). When objections are made, then, they tend to be much less formulaic and more deferential:

> Mr. Spurs: If she said to us she hit the car, can you explain why that might be?
> Mr. Rider: No, your Honor. With the greatest of respect, this lady cannot explain why anybody else said something.
> The Recorder:* That must be right. (* A part-time judge)

The contrasting form and frequency of objection sequences is indicative of a general difference in approach to adversariality in the two jurisdictions, which might be characterized as 'cooperative' and 'aggressive.' In the cooperative mode, English barristers are confined to their tables when they speak, dress in the same manner, and tend to resolve disagreements privately rather than make public objections. Jurors are imposed by the court rather than selected adversarially, and the defense does not present a counter opening statement. Judges take a more active role in ensuring that proceedings are civil and flow smoothly and then assist the jury by summarizing the evidence before deliberation. Research with mock jurors suggests that the more cooperative English trial procedures allow better recall of trial evidence and lead to a perception that the trial was more civil and fairer than American trials (Collett and Kovera, 2003). On the other hand, there is a greater risk of both nonverbal and verbal influence from the more powerful judge.

The Persuasive Context and Closing Arguments

Clearly, the central goal of trial lawyers is to persuade the jury and judge of their case. This persuasion process, then, occurs throughout the trial, either overtly or covertly. In opening statements, counsel persuade in part through their construction of narrative. In witness examination, they exploit the asymmetrical speaking rights and clear power differential to put across their case to the jury fairly covertly. This is

achieved both through the strategic use of questions and through a wide range of other pragmatic strategies designed to enhance or diminish the credibility of the witness ('person targeted') or influence the perception of the targeted events themselves ('idea targeted') (Gibbons, 2003: 112). These include, among others, the strategic use of silence and interruption, presupposition in the question, reformulation of the witness's answer in a more negative light, and the use of address forms and personal pronouns to create solidarity or distance.

The closing argument, though, is the phase of the trial where the persuasion process is most overt and most adversarial. Although we are lacking clear empirical evidence of its effect on the jury, trial lawyers tend to attribute great importance to the speech and to see it as their main performance event in the trial (Walter, 1988). Here advocates recount the story of the trial as well as the story in the trial. As elsewhere in the trial, persuasion in closing arguments can occur at all linguistic levels, from subtle phonetic features, through lexical and grammatical choice, to higher levels of discourse organization.

Equally important in the persuasion process is the integration of the verbal and the visual. Advocacy manuals stress the importance of visual evidence during witness examination, in the form of realia, photographs, maps, and diagrams which illustrate and bring to life the witness's account. In one of the closing arguments of the O. J. Simpson criminal trial, the prosecutor famously constructed a jigsaw puzzle which made up a picture of the 'murderer.' Even without sophisticated visual aids, though, advocates can integrate the verbal and visual through metaphor. Defense lawyers often talk of the *picture* or *impression* created by the evidence. Cotterill (2003: 208–217) shows how the prosecution and defense in the O. J. trial both use the 'jigsaw puzzle' metaphor to argue their respective cases. While the jigsaw is visually effective, it does have the weakness that there are always missing pieces of evidence. Consequently, Marcia Clark attempts to persuade the jury that those pieces are peripheral to the central picture (Cotterill, 2003: 216–217):

> In order to get the picture, to know what a jigsaw puzzle is depicting, if you're missing a couple of pieces of the sky, you still have the picture. You know, for example, it shows a house and, you know, and a dog and a kid in the yard and that sort of thing, you can see the picture. You miss a couple of pieces of the sky sometimes, you do lose those pieces, no big deal. You've got the picture ... you've got all the necessary pieces of the puzzle ...

On the other hand, the defense note that 'the prosecution took a photograph or picture of O. J. Simpson first, then they took the pieces apart' (Cotterill, 2003: 218), essentially accusing the prosecution of finding the evidence to fit the picture.

The jury's impression of counsel, protagonists in the story of the trial, can be an important part of the persuasion process. Consequently, impression management is an important rhetorical strategy, as Hobbs (2003) shows in an analysis of a U.S. prosecutor's rebuttal argument (one delivered after the defense closing in some U.S. jurisdictions). However, it is wrong to think that trial lawyers focus solely on the narrative aspects of the trial in their closings. They also attempt to bridge the gap between storytelling and the legal categories to which the jury will have to fit the evidence. Indeed, there is some empirical evidence to suggest that 'legal-expository' closing arguments, in which legal elements are outlined along with the evidence that supports or fails to support those elements, might be more effective for both plaintiffs and defendants in civil jury trials than narratively organized closings (Spiecker and Worthington, 2003).

The Pedagogic Context and Summing-up

This last point suggests a context to jury trial which is generally overlooked: its pedagogic aspect. When jurors come to their task, they might have little understanding of the law, trial procedure, or the forensic sciences. If they are to perform their task well, they will have to learn a great deal in a short time. While examining counsel are expected to get across technical concepts as clearly as possible, judges appear to lack the same obligation to communicate legal concepts and procedures effectively. Jury instructions are infamous for their complex and often archaic legal language which, in many U.S. jurisdictions, has to be read out verbatim.

Even where judges are permitted some linguistic discretion, they will not always accommodate the lay participants. In a detailed study of the taking of guilty pleas, Philips (1998) distinguished two types of judges: 'procedure-oriented' and 'record-oriented.' While the former will tailor the plea-taking procedure to the perceived due process needs of the particular defendant, the latter are concerned to standardize that procedure so that they will not be overturned at appeal. The result is that defendants are less likely to understand their rights. Similarly, Heffer (2002) found that English judges, given a model of the burden and standard of proof instructions in relatively plain English, will either accommodate even more to lay language or will revert back to a more legal wording. The same phenomenon can be observed at an

institutional level: higher tribunals in many U.S. states appear to focus more on issues of standardization, while the English Court of Appeal is more apt to allow judges to tailor the jury instruction process to the needs of the lay jury.

The tension between legal standardization and effective communication can also be seen in the different approaches to the summing-up of evidence. Most U.S. state jurisdictions do not allow judges to review or comment on the evidence. This ensures consistency and eliminates the danger of judicial bias influencing the jury's decision, one of the main criticisms of the English summing-up (Robertshaw, 1998). On the other hand, jurors are given no help in the difficult task of applying the law to the evidence. In discussing a 'strong' Tasmanian rape case that led to a hung jury, Henning notes that:

> . . . in the foreign and weighty circumstances of a criminal trial, it can be easy for lay people with little experience of trials to misjudge or misestimate the significance of particular matters, to lose sight of the wood for the trees (Henning, 1999: 212–213).

He thus stresses the need to guide the jury to 'a proper evaluation of the evidence,' using organizational and rhetorical techniques appropriate to such guidance. Currently, when judges do make explicit comments on the evidence, they tend to hedge and disclaim to such an extent that it is often difficult to extract the evaluative point. The language of judicial comments is arguably unique, particularly in the way that judges disclaim their comments through the forms *you may think* and *it is a matter for you* (Heffer, 2005) and raises the question as to how such a unique form of discourse is received by jurors. However, in considering the possible effect of the linguistic strategies adopted by judges, it is impossible to separate that language from the nature of the evidence and the case. Where a case hinges on one officer's uncorroborated identification of the defendant, a comment on reliability, however hedged, is likely to be influential:

> I am certainly not going to suggest to you that because Constable Bowles is an experienced policeman that he is any more reliable than you or I or anybody else necessarily in identifying people. That would be a big mistake. What I do suggest is this. That one should take into account the fact that this was not a chance meeting between people who did not expect to meet each other. He was wholly interested in that car. That is, as I say, the only reason why he was there. So, it is a matter for you, but you may think that that is something that may cause his identification to be the more reliable. However, as I say, that is entirely a matter for you to assess.

Here the explicit comment on reliability is preceded by a number of clear evaluations supporting that comment: 'experienced policeman,' 'not a chance meeting,' 'wholly interested,' 'the only reason.' It is doubtful, then, whether the heavy disclamation in the last two sentences makes the comment any less influential.

There is a fine line, then, between guiding a jury to a reasoned evaluation of the evidence and influencing them unfairly. Yet to pretend there is no responsibility for guidance is to ignore the real difficulty of the jury's task.

The Moral Context and Sentencing

While judges are constrained in the nature of their comments during the evidential phase and the summing-up, they are quite free to express moral judgment and epistemic certainty in the act of sentencing. In Early Modern trials, it was not uncommon for the prosecutor to produce extremely negative characterizations of the defendant, as in this outburst from the Lord Chief Justice in the trial of Lady Lisle (Helsinki Corpus of Historical Texts):

> LCJ: Thou art a strange, prevaricating, shuffling, sniveling, lying rascal.

Analyzed according to the systemic–functional framework of JUDGEMENT, a semantic resource 'for construing moral evaluations of behavior' (Martin, 2000), this one comment reveals a full range of negative evaluations of social esteem and sanction:

> LCJ: Thou art a **strange** [– normality], **prevaricating** [– reliability], **shuffling** [– reliability/capacity], **sniveling** [– capacity], **lying** [– veracity] **rascal** [– propriety].

However, evidentiary rules now prevent cross-examiners from being so blunt, with the result that legal-professional judgment of others' behavior is construed lexically only rarely during most stages of the trial (Heffer, 2005). The nearest equivalent to the above that can be found in a modern corpus of crossexaminations is a negative suggestion that the defendant is lying again:

> Q. It is a lie that you are just telling this jury today, is it not, another lie?

On the other hand, it is still common in the act of sentencing for the judge to spell out the full extent of a defendant's moral impropriety:

> Your record as far as sexual offenses are concerned is **quite appalling**. Indeed, in this case on the last occasion when you appeared in front of me, I said, and I still think and believe, that your conduct was verging on the **satanic**. In relation to counts 8, 9, and 10, the rape, buggery, and false imprisonment, you behaved **quite atrociously**. You are an **evil** man and you are a **wicked** man.

Such moral outbursts do in fact serve a legal purpose because severity of punishment is linked to the "relative moral wickedness of different offenders" (Hart, 1962: 37). It is the lexical inscription of extreme moral wickedness (*quite appalling* [sexual offenses record]; *satanic* [conduct]; [behaving] *quite atrociously*; *evil* [man]; *wicked* [man]), which justifies institutionally and socially the life sentence handed down to the convicted.

There is a danger, though, in expressing moral or epistemic certainty in this way. Solan notes the tendency of appeals court judges, mindful of the severe consequences to the parties that their decisions will have, "to issue pronouncements as though there were no alternative" (1993: 13). Just as such judges will make out that their decisions are based on inviolable legal principle, so some lower court judges will tend to suggest, once the verdict is in, that the evidence presented before the court was incontrovertible. In sentencing six suspected IRA terrorists of the murder of 21 people in two pub bombings in Birmingham, United Kingdom, in 1974, the judge pronounced "You stand convicted on each of twenty-one counts, *on the clearest and most overwhelming evidence I have ever heard*." Given that the convictions of the Birmingham Six were finally quashed in 1991 after it had been proven that the evidence against them had been very weak indeed, one has to ask whether the evidence in the original trial really appeared so 'overwhelming' or whether the judge felt compelled to justify an essentially unsafe verdict.

Conclusion

While the bulk of research on the language of jury trial has focused on the interactional dynamics of witness examination and the legal wording of jury instructions, this entry has attempted to show that the field encompasses much more than this, and that there are rich veins open for future research. The complex context of jury trial makes it a fascinating site for linguistic analysis, but research in this area also has clear applications for both improving legal professional communication and reforming the jury trial system.

Lehiste, Ilse (b. 1922)

L Shockey, University of Reading, Reading, UK

© 2006 Elsevier Ltd. All rights reserved.

Ilse Lehiste was born on January 31, 1922 in Tallinn, Estonia. The Baltic countries suffered heavily in World War II, undergoing multiple occupation: accordingly, her first postgraduate degree was undertaken in Germany. She received her Doctorate of Philosophy at the University of Hamburg in 1948, having specialized in English and Old Norse philology and writing on Old Norse sources in the works of William Morris. She lectured at that institution until 1949, when she emigrated to the USA.

Having conducted a large part of her professional life in Estonian, Russian, and German, the young Ilse then launched into lecturing in English: she became an associate professor of Germanic Philology at Kansas Wesleyan in 1950. In 1951, she moved to Michigan, where she worked as Associate Professor of Languages at Detroit Institute of Technology. Six years later, she made a smaller move to Ann Arbor, where she became a research associate and graduate student in the Communication Sciences Laboratory of the University of Michigan. She received her Ph.D. in Linguistics in 1959. While at Michigan, she worked with Gordon Peterson who was head of the laboratory, and several of her early publications were done in collaboration with him. Her history of experimental investigation of suprasegmental aspects of spoken language dates from this time, as revealed by publications in the early 1960s on the acoustic–phonetic realization of juncture, stress, accent, intonation, and quantity. These works set the tone of much subsequent phonetic research by herself and others.

In 1963, Lehiste was appointed as Associate Professor at the Ohio State University in Columbus, becoming a full professor two years later. Through her success in obtaining research grants, she improved the Ohio State phonetics laboratory and in the years following supervised the research of many graduate students, a number of whom are, in the early 1990s, active in phonetic teaching and research in the USA and elsewhere. Though research was (and is) her activity of choice, she did not ignore teaching, specializing in courses in acoustic and articulatory phonetics and historical linguistics. Two of her books, *Readings in Acoustic Phonetics* (1967) and *Principles and Methods for Historical Linguistics* (1979, with Robert Jeffers) reflect these interests.

Her work in acoustic phonetics, while wide-ranging, has centered around investigating the salience of suprasegmental cues in spoken language, especially temporal ones. (It is probably no coincidence that she is a native speaker of a language with three degrees of phonemic length in both consonants and vowels and with related phonotactic restrictions.) Several experiments have dealt with changes in temporal structure when a linguistic unit is used in higher-order constructions, for example what happens temporally to a stem morph when it is embedded in longer and longer words (*stick, sticky, stickier*); what are the temporal cues for word boundaries (*why choose* versus *white shoes*); and what are the phonetic cues for disambiguation of grammatical structure (*lighthouse keeper* versus *light housekeeper*). The interrelation of timing and fundamental frequency as cues has also been a consistent theme, as typified by her experiments with Serbo–Croatian short and long tones. Her search for temporal units of speech production has provided fuel for the lively debate on the role of syllables, feet, and morae in phonological theory. Despite her interest in speech production, the majority of her investigations have been in speech and language perception. Her emphasis on the acoustic aspects of speech is based on the theory that the salient articulatory properties of spoken language can be recovered from the acoustic signal.

Her work in historical linguistics is a natural development of her early research on Germanic philology and of the practical observation of languages in contact in her native country. Several of her publications deal with areal phenomena in both written and spoken language.

Between 1963 and her retirement in 1987, Ilse Lehiste published four books (arguably the most influential of which, *Suprasegmentals*, appeared in 1970), five other monographs, about 100 articles,

Spiecker S & Worthington D (2003). 'The influence of opening statement/closing argument organizational strategy on juror verdict and damage awards.' *Law and Human Behavior 27(4)*, 437–456.

Though research was (and is) her activity of choice, she did not ignore teaching, specializing in courses in acoustic and articulatory phonetics and historical linguistics. Two of her books, *Readings in Acoustic Phonetics* (1967) and *Principles and Methods for Historical Linguistics* (1979, with Robert Jeffers) reflect these interests.

Her work in acoustic phonetics, while wide-ranging, has centered around investigating the salience of suprasegmental cues in spoken language, especially temporal ones. (It is probably no coincidence that she is a native speaker of a language with three degrees of phonemic length in both consonants and vowels and with related phonotactic restrictions.) Several experiments have dealt with changes in temporal structure when a linguistic unit is used in higher-order constructions, for example what happens temporally to a stem morph when it is embedded in longer and longer words (*stick, sticky, stickier*); what are the temporal cues for word boundaries (*why choose* versus *white shoes*); and what are the phonetic cues for disambiguation of grammatical structure (*lighthouse keeper* versus *light housekeeper*). The interrelation of timing and fundamental frequency as cues has also been a consistent theme, as typified by her experiments with Serbo–Croatian short and long tones. Her search for temporal units of speech production has provided fuel for the lively debate on the role of syllables, feet, and morae in phonological theory. Despite her interest in speech production, the majority of her investigations have been in speech and language perception. Her emphasis on the acoustic aspects of speech is based on the theory that the salient articulatory properties of spoken language can be recovered from the acoustic signal.

Her work in historical linguistics is a natural development of her early research on Germanic philology and of the practical observation of languages in contact in her native country. Several of her publications deal with areal phenomena in both written and spoken language.

Between 1963 and her retirement in 1987, Ilse Lehiste published four books (arguably the most influential of which, *Suprasegmentals*, appeared in 1970), five other monographs, about 100 articles,

and over 60 reviews. The majority of these were in experimental phonetics, but her work is also strongly represented in historical linguistics, Slavic and Finno–Ugric linguistics, and literary analysis and criticism. Retirement provided her with an opportunity to do yet more research, and she was in 1992 the recipient of a grant to investigate the phonetic realization of metrical structure in orally produced poetry. Though she would like to cover all the languages with which she is familiar, she limited herself (for this project) to English, Estonian, Swedish (as spoken both in Sweden and Finland), Finnish, Latvian, Lithuanian, Icelandic, Faroese, Serbo–Croatian, and Hungarian.

She is a member of over 20 learned societies and was president of the Linguistic Society of America in 1980. Her many honors include Honorary Doctorates from the University of Essex in 1977, from Lund University in 1982, and from Tartu University in 1989. She is a Fellow of the American Academy of Arts and Sciences.

Ilse Lehiste has, throughout her career, collected data in order to contribute to linguistic theory. Her interests lie not only in how speech is produced and perceived, but in what facts about speech can tell about the cognitive representation of language. Her attitude may be best deduced from a quotation from *Suprasegmentals*: 'A phonologist ignores phonetics at his own peril.'

In 1994, she won the Alumnae Athena Award from the University of Michigan; in 1998, she was elected as Foreign Member of the Finnish Academy of Science and Letters; and in 1999, she was awarded an Honorary Doctor of Humane Letters from Ohio State University. She was awarded the Order of the White Star, 3rd Class, by the Republic of Estonia in 2001; in 2002 she won the Medal for Scientific Achievement from the International Speech Communication Association; and in 2003 she won the Kay Elemetrics Award from the International Society of Phonetic Sciences. She gave the keynote address at the 2002 International Conference on Spoken Language Processing in Denver, Colorado; an invited paper at the 2004 International Conference: Speech Prosody, in Nara City, Japan (on 'Prosody in speech and singing'); and an invited paper at the 2004 International Symposium on Tonal Aspects of Languages in Beijing ('Bisyllabicity and tone').

Lehmann, Winfred Philipp (b. 1916)

E S Firchow, University of Minnesota, Minneapolis, MN, USA

© 2006 Elsevier Ltd. All rights reserved.

Winfred Philipp Lehmann was born on June 23, 1916, near Surprise, Nebraska, the son of a Lutheran minister. He spent his early childhood in a German-speaking community until 1919, when his family moved to an English-speaking parish. He attended Northwestern Academy High School in Wisconsin from 1928 to 1932, when he entered Northwestern College in Watertown, Wisconsin, where he studied liberal arts and comparative philology (B.A. 1936). Graduate studies in Germanic linguistics followed from 1937 to 1941 at the University of Wisconsin (Madison). There he studied with Einar Haugen, Roe-Merrill Heffner, Alexander Hohlfeld, Alfred Senn, and William Freeman Twaddell. He received his M.A. from the university in 1938 and his Ph.D. in 1941. In 1940, he married Ruth Preston Lehmann (née Miller), a professor of English at the University of Texas who specialized in Old English and Old Irish. She died in 2000.

From 1942 to 1946, Lehmann served in the American Army Signal Corps. In 1943, he became instructor and officer-in-charge at the Japanese Language School in Arlington, Virginia. In 1946, he joined the German faculty at Washington University in St Louis, leaving in 1949 to take up an associate professorship in Germanic languages at the University of Texas (Austin). In 1952, Lehmann was promoted to full professor, and from 1966 until his retirement in 1986 he also served as professor of linguistics. An able administrator, he chaired the department of Germanic languages from 1957 to 1964, and in 1961 became the director of the Linguistics Research Center. He was appointed Ashbel Smith Professor of Germanic Languages from 1963 to 1983, chaired the linguistics department from 1966 to 1972, and was Temple Centennial Professor in the Humanities from 1983 to 1986. He was well known for his good teaching, and his visiting professorships included the University of Marburg, Germany (1964); the University of Illinois, Urbana (Collitz Professor, 1968); and the State University of New York, Oswego (1976).

Lehmann has held numerous offices and received many honors. He was director of the Georgetown English Language Program in Ankara, Turkey (1955–1956); was named corresponding fellow of the Institute for German Language in Mannheim (1969); and in 1975 was made a member of the Royal Danish Academy of Sciences. In 1974, he served as chair of the linguistic delegation, and in 1981 as cochair of the Commission on Humanities and Social Sciences, to the People's Republic of China. From 1974 to 1978, Lehmann acted as chairman of the board of trustees for the Center for Applied Linguistics in Washington, DC. From 1979 to 1986, he acted as a member of the Advisory Board of the Guggenheim Memorial Foundation, and from 1972 to 1986 as secretary of the board of directors of the American Council of Learned Societies. He has held numerous fellowships, including a Fulbright (1950–1951) to Norway and a Guggenheim (1972–1973). He is a fellow of the American Association for the Advancement of Science (since 1963); received the Brothers-Grimm-Prize (Marburg 1974); holds honorary doctorates from the State University of New York, Binghamton (1985), and from the University of Wisconsin (1995); and in 1987 was awarded the Order of Merit (Commander's Cross) of the Federal Republic of Germany and the *Pro bene meritis* Award at the University of Texas.

Lehmann is a member of numerous scholarly societies, among them the Linguistics Society of America (president, 1973), Modern Language Association (president, 1987), South-Central Modern Language Association (president, 1982), Association for Computational Linguistics (president, 1964), and Linguistic Association of the Southwest (president, 1975).

His research interests center around Indo–European linguistics – particularly reconstruction, as well as the phonology and syntax of Proto-Indo-European. Originally trained in structural linguistics, Lehmann has broadened his interests to include general linguistics and the history and development of American linguistics. In the historical Germanic field, he traced the development of the Germanic verse form and investigated Gothic etymology (with H.-J. J. Hewitt, 1986) and Middle High German vocabulary (especially Walther von der Vogelweide, with R.-M. Heffner, 1940). Together with his wife Ruth Lehmann, he authored an introduction to Old Irish and to Biblical Hebrew (with E. Raizen and H.-J. J. Hewitt, 1999). Lehmann has also done a great deal to further the teaching of German in the English-speaking world, including contributing to a widely used textbook for beginning German (with H. Rehder and G. Schulz-Behrend, 1962). He has published in English, German, and Russian.

Lehmann's numerous publications include *Historical linguistics* (1962), *Descriptive linguistics* (1972), *Theoretical bases of Indo-European linguistics* (1993), *Pre-Indo-European* (2002), as well as many edited collections, essays, and reviews in scholarly journals. He was honored by *Festschriften* in 1977, 1992, and 1999. His biographies appear in *Who's Who in the World*, *Who's Who in America*, *Who's Who in Science and Engineering*, *Who's Who in American Education*, *Who is Who in the South and Southwest*, *Wer ist Was in der Sprachwissenschaft*, and *Internationales Germanistenlexikon (1800–1950)*.

Leibniz, Gottfried Wilhelm (1646–1716)

M Piot, Université Stendhal-Grenoble 3, Grenoble, France

© 2006 Elsevier Ltd. All rights reserved.

Gottfried Wilhelm Leibniz (**Figure 1**) was a German philosopher (the designer of one of the great systems of philosophy), mathematician (co-inventor, independently of Isaac Newton, of differential and integral calculus), logician, scientist, diplomat, librarian, lawyer, historian, and linguist. He is often described as the last universal genius: a thinker whose range extended to all that was known in his day.

He was born in Leipzig, Germany, on June 1, 1646, of Slavic descent, the son of Frederick Leibniz, a jurisconsult and professor of moral philosophy at the University of Leipzig, and of Catherine Schmuck, the daughter of a doctor and professor of law. In 1600, the emperor Rodolf conferred on his great-uncle, a fighting captain in Hungary, a title of nobility and the arms Leibniz bore. His father died before he was 6 years old, and his mother took care of his education. By the time he was 12, he had taught himself to read Latin easily, and had begun Greek with the great library he had inherited from his father. Intellectually precocious, he entered the University of Leipzig at the age of 15 as a law student, obtaining his baccalaureate in 1663. Before he was 20, he had mastered the ordinary textbooks on mathematics, philosophy, theology, and law. In 1666, the University of Leipzig declined to confer the degree of doctor of law upon him, because of his youth, and he went instead to the University of Altdorf (near Nuremberg), where his dissertation gained him not only the doctorate, but the offer of a professorship. An essay written on the study of law was dedicated to the Elector of Mainz, and led to his appointment by the elector, from which he was subsequently promoted to the diplomatic service.

Figure 1 Gottfried Wilhelm Leibniz.

In the latter capacity, Leibniz drew up a scheme proposing to offer German cooperation. In 1672, Leibnitz went to Paris on the invitation of the French government to explain the details of the scheme, but nothing came of it. At Paris (until 1676), he met the French philosophers Malebranche and Arnauld and studied Pascal's mathematical works; he also met the astronomer and mathematician Huygens and their conversation led Leibnitz to study geometry, which he described as opening a new world to him, although he had already written tracts on various minor points in mathematics, the most important being a paper on combinations written in 1668, and built a working model of an arithmetical calculating machine (the basis of his election to the Royal Society in 1673). This was the first mechanical calculator capable of multiplication and division (improving Pascal's first calculating machine, capable of addition and subtraction). He also developed the modern form of the binary numeral system used in the digital computer.

Gottfried Wilhelm Leibniz (Figure 1) was a German philosopher (the designer of one of the great systems of philosophy), mathematician (co-inventor, independently of Isaac Newton, of differential and integral calculus), logician, scientist, diplomat, librarian, lawyer, historian, and linguist. He is often described as the last universal genius: a thinker whose range extended to all that was known in his day.

He was born in Leipzig, Germany, on June 1, 1646, of Slavic descent, the son of Frederick Leibniz, a jurisconsult and professor of moral philosophy at the University of Leipzig, and of Catherine Schmuck, the daughter of a doctor and professor of law. In 1600, the emperor Rodolf conferred on his great-uncle, a fighting captain in Hungary, a title of nobility and the arms Leibniz bore. His father died before he was 6 years old, and his mother took care of his education. By the time he was 12, he had taught himself to read Latin easily, and had begun Greek with the great library he had inherited from his father. Intellectually precocious, he entered the University of Leipzig at the age of 15 as a law student, obtaining his baccalaureate in 1663. Before he was 20, he had mastered the ordinary textbooks on mathematics, philosophy, theology, and law. In 1666, the University of Leipzig declined to confer the degree of doctor of law upon him, because of his youth, and he went instead to the University of Altdorf (near Nuremberg), where his dissertation gained him not only the doctorate, but the offer of a professorship. An essay written on the study of law was dedicated to the Elector of Mainz, and led to his appointment by the elector, from which he was subsequently promoted to the diplomatic service.

Figure 1 Gottfried Wilhelm Leibniz.

In the latter capacity, Leibniz drew up a scheme proposing to offer German cooperation. In 1672, Leibnitz went to Paris on the invitation of the French government to explain the details of the scheme, but nothing came of it. At Paris (until 1676), he met the French philosophers Malebranche and Arnauld and studied Pascal's mathematical works; he also met the astronomer and mathematician Huygens and their conversation led Leibnitz to study geometry, which he described as opening a new world to him, although he had already written tracts on various minor points in mathematics, the most important being a paper on combinations written in 1668, and built a working model of an arithmetical calculating machine (the basis of his election to the Royal Society in 1673). This was the first mechanical calculator capable of multiplication and division (improving Pascal's first calculating machine, capable of addition and subtraction). He also developed the modern form of the binary numeral system used in the digital computer.

Along with Newton, Leibniz is credited with inventing infinitesimal calculus in the 1670s (a mathematical foundation of modern science and engineering) and is given particular credit for his development of the integral and the product rule. Although there is some question of original authorship, at the end of the 18th century, the prevalent opinion – except the French philosopher Fontenelle – was against Leibnitz. Based on his many published and unpublished papers, today the majority of writers tend to think it more likely that the inventions were independent. He introduced several notations used in calculus to this day, for instance the integral sign representing an elongated *S* from the Latin word *summa* and the *d* used for differentials from the Latin word *differentia*. Leibniz is also credited with the term 'function' (1694), which he used to describe a quantity related to a curve; such as a curve's slope or a specific point of said curve.

In 1673, the Elector of Mainz died, and Leibnitz entered the service of the Brunswick family. In 1676 he again visited London, and then moved to Hannover, where, until his death, he occupied the well-paid post of librarian in the ducal library. His memoranda on the various political, historical, and theological questions concerning the Hanoverian family and dynasty of 40 years (1673–1713) form a valuable contribution to the history of that time.

He was fascinated by the application of technology to the solution of both practical and theoretical problems, the method he used to work on the hydraulic press, windmills, lamps, submarines, clocks, carriages, water pumps, and so on. As a physicist, he made advances in mechanics, specifically the theory of momentum.

He also made contributions to linguistics, history, esthetics, and political theory.

He dedicated much of his work to the systematic organization of existing knowledge across the disciplines: he worked to establish major libraries and organize scientific societies (in Berlin and Vienna). In 1700, the German Academy of Sciences of Berlin was created on his advice, and he drew up the first body of statutes for it; he was also named foreign member of the French Academy of Sciences in Paris. In 1714, on George I's ascension to the throne of England, Leibniz was thrown aside; he was forbidden to come to England, and the last 2 years of his life were spent in neglect. He died on November 14, 1716, in Hannover. His contributions on a vast array of subjects are found scattered in obscure journals, in hundreds of correspondences (with the leading intellectual and political figures of his era), and in a huge collection of unpublished manuscripts, the majority of which are preserved in the Lower Saxony State Library in Hannover.

Leibniz occupies at least as large a place in the history of philosophy as he does in the history of mathematics. Throughout his life, he hoped that his work on philosophy (as well as his work as a diplomat) would form the basis of a theology capable of reuniting the Church, divided since the Reformation in the 16th Century. Similarly, he was willing to engage with, and borrow ideas from, the materialists as well as the Cartesians, the Aristotelians as well as the most modern scientists. Leibniz is known among philosophers for his wide range of thought on fundamental philosophical ideas and principles, including truth, necessary and contingent truths, possible worlds, the principle of sufficient reason (i.e., that nothing occurs without a reason), the principle of pre-established harmony (i.e., that God constructed the universe in such a way that corresponding mental and physical events occur simultaneously), and the principle of noncontradiction (i.e., that any proposition from which a contradiction can be derived is false). Leibniz's view that ours is the best of all possible worlds has been vigorously debated. Voltaire, after being attracted in *Zadig*, parodied Leibniz's solution in his other famous novel *Candide*.

His philosophical contribution to metaphysics is based on the *Monadologia*, which introduces 'monads' as 'substantial forms of being,' which are akin to spiritual atoms, eternal, indecomposable, individual, following their own laws, not interacting ('windowless') but each reflecting the whole universe in pre-established harmony. The notion of a monad solves the problem of the interaction of mind and matter that arises in Descartes' system, as well as the individuation that seems problematic in Spinoza's system, which represents individual creatures as mere accidental modifications of the one and only substance. During this period in philosophy, innate ideas tended to be opposed to the thorough-going empiricism of Locke. Like Descartes before him – and for many of the same reasons – Leibniz found it necessary to posit the existence of innate ideas. Leibniz's most extensive discussion of innate ideas, not surprisingly, is in the *Nouveaux essais sur l'entendement humain* (1705), the most important source for Leibniz's philosophy of language, a polemical writing directed against Locke's *An essay concerning human understanding*. Now, at the metaphysical level, since monads have no 'windows,' it must be the case that all ideas are innate. That is to say, an idea in every monad/soul is just another property of that

monad, which happens according to an entirely internal explanation represented by the complete concept. But at the phenomenal level, it is certainly the case that many ideas are represented as arriving through my senses. In general, at least any relation in space or time will appear in this way. For Leibniz, the location of an object is not a property of an independent space, but a property of the located object itself – and also of every other object relative to it. It is also worth pointing out that Leibniz (and after him Kant) continued a long tradition of philosophizing about space and time from the point of view of space – as if the two were always in a strict analogy. Space and time are not in themselves real, are not substances, are ideal. Space and time are just ways (metaphysically illegitimate ways) of perceiving certain virtual relations between substances. They are 'phenomena.'

On comparative philology and linguistics, Leibniz's inquiries into the origin and the development of languages were connected with his interest in the history of the peoples and nations of Europe. He held that an original language could not be found among the languages that were known (the only exception being Chinese) and proposed etymological principles, so that they would be used in historical linguistics, and criticized what he considered to be etymologically unsound reasoning.

Leibniz had a lifelong interest in and pursuit of the idea that the principles of reasoning could be reduced to a formal symbolic system, an algebra or calculus of thought, in which controversy would be settled by calculations.

In Leibniz's time, several proposals for the construction of an artificial 'universal language' existed. Two goals to be achieved by putting such a language into practice were first to overcome language barriers, and second to have a language that was more efficient and easier to learn than existing ones. Furthermore, these artificial languages were meant to incorporate an accurate representation of knowledge, so that learning the language would entail acquiring knowledge of the world of nature. Before putting forward his project for a *Characteristica Universalis*, Leibniz had studied both Dalgarno's and Wilkins's work very carefully. Although he rightly emphasized that the language he envisaged differed fundamentally from the languages constructed by his English precursors, he made use of their work in executing his own plans. He took the Aristotelian categories as a starting point just as Dalgarno and Wilkins had done, but he proposed a thorough revision of this theory, giving more prominence to combinatorial principles than to classificatory ones. Like the other proposals, its starting point was to be an analysis of concepts, backing up the nominal definitions of the signs of the language. His innovation was that the concepts would be coded as numbers. Reasoning could then be reduced to *Calculus Ratiocinator* (numerical calculation). Leibniz's rational grammar project, which was aimed at explicating the semantics of natural language expressions so as to determine their logical structure, deserves to be further explored. Some scholars now suggest that Leibniz should be regarded as one of the first thinkers to envision something like the idea of artificial intelligence. It is clear that Leibniz, like contemporary cognitive scientists, saw an intimate connection between the form and content of language and the operations of the mind. He believed that such a language would perfectly mirror the processes of intelligible human reasoning. This view of Leibniz's led him to formulate a plan for a universal language, an artificial language composed of symbols, which would stand for concepts or ideas, and logical rules for their valid manipulation. Leibniz's writings about this project (which, it should be noted, he never got the chance to actualize) reveal significant insights into his understanding of the nature of human reasoning. This understanding, it turns out, is not that different from contemporary conceptions of the mind, as many of his discussions bear considerable relevance to discussions in the cognitive sciences.

Michel Lejeune, born in Paris in 1907, was educated in Classics in the École Normale Supérieure, and soon joined the seminars of Joseph-Jean-Baptiste-Marie Vendryes and other comparativists in the École Pratique des Hautes Études. Received as *agrégé de grammaire*, he later became a lecturer in Greek and Latin philology at Poitiers University, and then a professor at Bordeaux University (from 1937 on), where he was later chosen as the dean of the faculty of arts. Elected as *directeur d'études* in the École Pratique des Hautes Études (in Indo-European Comparative Grammar), he came back to Paris. He acted as the director for Human Sciences in the C.N.R.S. (French Research Foundation) from 1955 to 1963. He entered the Académie des Inscriptions et Belles-Lettres in 1963. Leader of the French comparativists, he left a prolific and important amount of studies (some 20 books and 300 articles).

His scientific interests ranged from ancient Greek and Mycenean to Celtiberian, from Etruscan to Phrygian, with a clear preference for Italic and ancient Celtic dialects. Attracted by the epigraphical difficulties, he was led to edit texts in minor Indo-European dialects, which had been previously discarded as undecipherable or unusable for comparative purposes. His work brought to light some Indo-European dialects, which were previously misunderstood, either in their phonetic composition or in their dialectal affinities, such as Lepontic and Venetic.

His first publications dealt with ancient Greek dialects: as a thesis, he wrote a linguistic analysis of Delphic manumission texts. His teaching of Greek led him to publish a small handbook on Greek accentuation, and then an important phonetic history of Greek, with both comparative and dialectal analysis (1947; a revised edition, incorporating Mycenean sources, was published in 1972). Associated with the discoveries of Ventris and Chadwick from the start, he made a substantial contribution to the progress of Mycenean studies, with more than 50 articles (reprinted in *Mémoires de philologie mycénienne*, 3 vols, 1958–1973). This type of study, associating epigraphy and linguistics, appealed very much to his analytical mind: facts had to be carefully and rationally identified, through methodical classification and comparison; but also new facts were available that could invalidate established theories.

He applied the same careful method to other epigraphies: Celtiberian, on which he published a monograph in 1956, Lepontic and Cisalpine Gaulish (1971), Venetic (1974), Gallo-Greek (1985) etc. A linguistic problem he frequently dealt with was anthroponymy: a precise classification of names can result in important information on family structures. For the sake of clarity he invented such terms as 'idionyms' (for simple individual names) and 'gamonyms' (the reference to the spouse, in Venetic).

His conception of epigraphical study included a thorough understanding of the script, as well as a clear analysis of the linguistic data. All his epigraphical studies provide an important contribution to the history of writing. Reused alphabets, and particularly the use of the Greek alphabet for non-Greek languages, were a constant interest in his scientific research: these offered him the opportunity of a new phonological analysis, searching for the analysis made by the inventors of these alphabets. He published important epigraphic corpora for three of these languages, Phrygian, South Oscan (Osco-Greek), and South Gaulish (Gallo-Greek).

Lenneberg, Eric H. (1921–1975)

J-M Fortis, CNRS, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Eric Heinz Lenneberg (Figure 1) was born in 1921 in Düsseldorf, Germany. His father was a physician. He moved to Brazil in 1933, when Hitler came to power, where he stayed until 1945, before settling in the United States. He graduated from Harvard in 1955 (in psychology and language) before turning to neurology during his postgraduate years as a fellow of the Russell Sage Foundation. His career can be divided into three periods: from 1953 to 1960–1962, his interest was directed toward the linguistic categorization of color and its cognitive consequences. From 1962 to 1965, he turned to the study of language acquisition. After this date, he scaled up the scope of his investigations and embarked on the more ambitious project of describing the biological determinants of language. Most of Lenneberg's ideas are compiled in the groundbreaking book he published in 1967, his *Biological foundations of language*. His academic career was spent at Cornell University. He died in New York in 1975.

One of Lenneberg's initial motivations was the desire to test empirically the Sapir-Whorf hypothesis of a correspondence (or even a causal dependence) between linguistic structures and cognitive representations. In collaboration with Roger Brown, he chose a domain that he believed to be amenable to experimentation: colors. A number of experiments on color categorization were conducted, showing that recognition of a color was positively related to an index called *codability*, which in fact measured the degree to which subjects agreed in naming a given color. At the time, his nominalist inclinations were witnessed by the fact that he neglected the influence of perceptual discriminability, thus attributing to codability the bulk of the facilitation effect. He was also preoccupied with intercultural comparison, and, in collaboration with the anthropologist John Milton Roberts, he extended his research on colors to Zuni classification (the Zunis are an Indian tribe on the New Mexico-Arizona border). As for English-speaking subjects, recognition was found to be correlated with linguistic discriminations. The stability of colors perceived as focal across subjects and cultures (which was also observed by Eleanor Heider-Rosch during the time of Lenneberg) led him, among other arguments, to adopt a perspective which he described as *Neo-Kantian*. In this perspective, concepts (including linguistic concepts) reflect the structure that orders "impinging physical stimuli in a predetermined and species-specific way" (Lenneberg, 1962: 105). This move was in line with the nativist ideas on language that he was to propose shortly after. Lenneberg's experiments, with their emphasis on terms referring to perceptual qualities, set the agenda for much subsequent work on the linguistic relativity of cognitive representations (Lucy, 1992).

Figure 1 Eric Heinz Lenneberg (1921–1975).

His work at the Children's Hospital Medical Center in Boston gave Lenneberg the opportunity to explore another facet of the relation between biology and language, namely the relation of language development to cerebral maturation. His observations led him to the conclusion that the compelling force that drives language acquisition is internal and biological; a minimal exposure is needed, of course, and this exposure must occur before a critical age, between 2 and the early teens. This conclusion, for which he argues at length in his main opus of 1967, is widely known today as the Critical Period Hypothesis. Lenneberg's arguments are based on the pattern of recovery from aphasic disturbances or sudden deafness in children. They also rest on the fact that hearing children born to deaf parents do not even suffer a delay in the course of language development, provided they have been minimally exposed to language before this critical age. Particularly striking for Lenneberg was the fact that the maturation of the brain reaches an asymptote concomitantly with this critical age. However, he was cautious not to postulate a direct causal relationship between the maturation of the brain and the course of language development. He merely suggested that the maturation of the brain would set limits on what can be learned.

As for the cerebral localization of speech functions, Lenneberg's stance seems to be that of a skeptic with holistic proclivities. Obviously, he was much impressed by the observations of Penfield and Roberts, who were initiating the technique of electrostimulation to map the language areas of the brain. Penfield and Roberts had shown the point-like, disseminated character of the areas where electrical stimulation interferes with speech. Such results led Lenneberg to reject any strict localization of language, beyond a left–right asymmetry and an anterior–posterior polarization, respectively, of motor and sensory aspects of language.

In his 1967 book, Lenneberg also reiterates Lashley's arguments for the need of central regulatory mechanisms involved in the coordination of complex movements. In particular, Lenneberg shows that sequential association of nervous signals can in no way account for the production of speech (which parallels Chomsky's contemporary attack on sequential models of grammar). Although speech production is centrally regulated, Lenneberg also claims that it must adjust to a fixed rhythmic pattern providing temporal slots for the sequencing of phonemes. This last point appears quite important: in the eyes of Lenneberg, the specificity of language resides to a certain extent in its timing mechanisms.

Lenneberg's ideas are often considered to be supportive of the Chomskyan language organ, or language acquisition device. It is unclear whether Lenneberg regarded language as a very specialized skill with a specific substrate. But it can be said that language was for him a species-specific capacity, whose development was internally driven, given a minimal amount of exposure. In this respect, he does offer support for the language organ hypothesis.

Leont'ev, Aleksei Alekseevich (1936–2004)

O Thomason, University of Georgia, Athens, GA, USA

© 2006 Elsevier Ltd. All rights reserved.

Aleksei Alekseevich Leont'ev (also spelled Leontiev and Leontyev) was born on January 14, 1936, in Moscow, and died in Moscow on August 12, 2004. He received a Ph.D. in linguistics in 1968 and in psychology in 1975. He was a winner of the Lomonosov Prize, a member of the Russian Academy of Education (1992), an honorary president of the L. S. Vygotsky Psycholinguistic Society (from 1991), a professor in the psychology department at M.V. Lomonosov Moscow State University (from 1998), an author and a supervisor of the educational program 'Shkola 2100' (from 1996), and a member of many councils and editorial boards of international and Russian journals.

After graduating from M. V. Lomonosov Moscow State University with a B.A. in German language (1958), Leont'ev worked in the Linguistic Institute of the Academy of Science USSR, where he conducted research in linguistics (his dissertations were entitled ('General linguistic views of I. A. Baudouin de Courtenay') and ('The theoretical problems of the speech act psycholinguistic modeling') and later in psychology ('The psychology of speech')). Leont'ev's areas of interest were general psychology, the psychology of speech, psycholinguistics, methods of teaching native and foreign languages, general linguistics, the history of linguistics, ethnography, and poetics.

Leont'ev was the son of the famous Russian psychologist A. N. Leont'ev, who was a student of L. S. Vygotsky. Leont'ev continued his father's research in psychology and became one of the founders of the Russian psychological school, which was based on the theoretical works of L. S. Vygotsky, A. N. Leont'ev, A. R. Lurija, and the linguistic tradition developed by L. V. Shcherba. Leont'ev was opposed to the Behaviorist theory and considered speech not to be a passive succession of vocal reactions, but a dynamic and purposeful vocal activity. He stressed the active nature of speech processes and pointed out that speech was strongly conditioned by social factors.

As for the cerebral localization of speech functions, Lenneberg's stance seems to be that of a skeptic with holistic proclivities. Obviously, he was much impressed by the observations of Penfield and Roberts, who were initiating the technique of electrostimulation to map the language areas of the brain. Penfield and Roberts had shown the point-like, disseminated character of the areas where electrical stimulation interferes with speech. Such results led Lenneberg to reject any strict localization of language, beyond a left–right asymmetry and an anterior–posterior polarization, respectively, of motor and sensory aspects of language.

In his 1967 book, Lenneberg also reiterates Lashley's arguments for the need of central regulatory mechanisms involved in the coordination of complex movements. In particular, Lenneberg shows that sequential association of nervous signals can in no way account for the production of speech (which parallels Chomsky's contemporary attack on sequential models of grammar). Although speech production is centrally regulated, Lenneberg also claims that it must adjust to a fixed rhythmic pattern providing temporal slots for the sequencing of phonemes. This last point appears quite important: in the eyes of Lenneberg, the specificity of language resides to a certain extent in its timing mechanisms.

Lenneberg's ideas are often considered to be supportive of the Chomskyan language organ, or language acquisition device. It is unclear whether Lenneberg regarded language as a very specialized skill with a specific substrate. But it can be said that language was for him a species-specific capacity, whose development was internally driven, given a minimal amount of exposure. In this respect, he does offer support for the language organ hypothesis.

Leont'ev, Aleksei Alekseevich (1936–2004)

O Thomason, University of Georgia, Athens, GA, USA

© 2006 Elsevier Ltd. All rights reserved.

Aleksei Alekseevich Leont'ev (also spelled Leontiev and Leontyev) was born on January 14, 1936, in Moscow, and died in Moscow on August 12, 2004. He received a Ph.D. in linguistics in 1968 and in psychology in 1975. He was a winner of the Lomonosov Prize, a member of the Russian Academy of Education (1992), an honorary president of the L. S. Vygotsky Psycholinguistic Society (from 1991), a professor in the psychology department at M.V. Lomonosov Moscow State University (from 1998), an author and a supervisor of the educational program 'Shkola 2100' (from 1996), and a member of many councils and editorial boards of international and Russian journals.

After graduating from M. V. Lomonosov Moscow State University with a B.A. in German language (1958), Leont'ev worked in the Linguistic Institute of the Academy of Science USSR, where he conducted research in linguistics (his dissertations were entitled ('General linguistic views of I. A. Baudouin de Courtenay') and ('The theoretical problems of the speech act psycholinguistic modeling') and later in psychology ('The psychology of speech')). Leont'ev's areas of interest were general psychology, the psychology of speech, psycholinguistics, methods of teaching native and foreign languages, general linguistics, the history of linguistics, ethnography, and poetics.

Leont'ev was the son of the famous Russian psychologist A. N. Leont'ev, who was a student of L. S. Vygotsky. Leont'ev continued his father's research in psychology and became one of the founders of the Russian psychological school, which was based on the theoretical works of L. S. Vygotsky, A. N. Leont'ev, A. R. Lurija, and the linguistic tradition developed by L. V. Shcherba. Leont'ev was opposed to the Behaviorist theory and considered speech not to be a passive succession of vocal reactions, but a dynamic and purposeful vocal activity. He stressed the active nature of speech processes and pointed out that speech was strongly conditioned by social factors.

He researched different problems in communication, and for the first time in Russian psychology presented a monographic work ('Psixologiia obshcheniia') devoted to the psychological theory of speech (1974). He also worked on problems of speech influence in commercials and newspapers in the former USSR. Leont'ev was interested in associative experiments and published one of the first dictionaries of associative norms in a language (1977). Leont'ev was concerned with problems of language planning, education, and teaching Russian as a foreign language. He was one of the founders and a leader of the group that created the interregional public organization that helped develop and introduce a new educational program, 'Shkola 2100,' in Russia and parts of the former Soviet Union in 1999. This program is primarily concerned with the work of kindergartens and middle schools and is expected to run for 10 years (till 2010).

Leont'ev is the author of some 600 publications, which have both theoretical and practical value. His works have been translated into 30 different languages. His research was notable for using information from different fields of the humanities and applying this knowledge to other areas (for example, his work 'Rech v kriminalistike i sudebnoi psixologii' (Leont'ev *et al.*, 1977). Leont'ev gave the first detailed description of the Papuan languages and Tok Pisin in Russian linguistics. He was also the first publisher of many works written by I. A. Baudouin de Courtenay, E. D. Polivanov, L. P. Jakubinsky, L. S. Vygotsky, and A. N. Leont'ev.

Lepsius, Carl Richard (1810–1884)

S Pugach, The Ohio State University, Lima, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Karl Richard Lepsius, also known as Richard Lepsius, was born on December 23, 1810, in Naumburg, Thuringia, and died on July 10, 1884, in Berlin. His parents were Carl Peter Lepsius and Friederike Gläser. Lepsius was to distinguish himself as both a philologist and an archaeologist, and in that sense he followed in the footsteps of his father, a financial procurer who had founded the Thuringia-Saxon Archaeological Society. Lepsius demonstrated linguistic talent as early as *Gymnasium*, where he wrote a class theme on the significance of Sanskrit to comparative philology. He went to university in Leipzig, Göttingen, and Berlin, where he continued to study philology and archaeology, subjects that he considered so closely related that he had difficulty choosing which to pursue. In Göttingen Lepsius became acquainted with philologist and folklorist Jacob Grimm (*see* **Grimm, Jacob Ludwig Carl (1785–1863)**) and his brother Wilhelm, while in Berlin he worked with comparative philologist Franz Bopp (*see* **Bopp, Franz (1791–1867)**) and theologian Friedrich Schleiermacher. From Berlin Lepsius proceeded to Paris, where he studied the works of Jean-François Champollion, the first scholar to decipher the Rosetta stone (*see* **Champollion, Jean-Francois (1790–1832)**). Lepsius researched hieroglyphics, too, and in 1837 demonstrated that the letters of its pictographic alphabet were polysyllabic. While Lepsius was an expert philologist, he was also an historian and Egyptologist, and he became professor of Egyptology in Berlin in 1842. From Berlin Lepsius led an archaeological expedition to Nubia and

Karl Richard Lepsius, also known as Richard Lepsius, was born on December 23, 1810, in Naumburg, Thuringia, and died on July 10, 1884, in Berlin. His parents were Carl Peter Lepsius and Friederike Gläser. Lepsius was to distinguish himself as both a philologist and an archaeologist, and in that sense he followed in the footsteps of his father, a financial procurer who had founded the Thuringia-Saxon Archaeological Society. Lepsius demonstrated linguistic talent as early as *Gymnasium*, where he wrote a class theme on the significance of Sanskrit to comparative philology. He went to university in Leipzig, Göttingen, and Berlin, where he continued to study philology and archaeology, subjects that he considered so closely related that he had difficulty choosing which to pursue. In Göttingen Lepsius became acquainted with philologist and folklorist Jacob Grimm (*see* **Grimm, Jacob Ludwig Carl (1785–1863)**) and his brother Wilhelm, while in Berlin he worked with comparative philologist Franz Bopp (*see* **Bopp, Franz (1791–1867)**) and theologian Friedrich Schleiermacher. From Berlin Lepsius proceeded to Paris, where he studied the works of Jean-François Champollion, the first scholar to decipher the Rosetta stone (*see* **Champollion, Jean-Francois (1790–1832)**). Lepsius researched hieroglyphics, too, and in 1837 demonstrated that the letters of its pictographic alphabet were polysyllabic. While Lepsius was an expert philologist, he was also an historian and Egyptologist, and he became professor of Egyptology in Berlin in 1842. From Berlin Lepsius led an archaeological expedition to Nubia and

Egypt that was funded by the Prussian state. Much of Lepsius's expedition was devoted to transcribing and interpreting Egyptian inscriptions. He wrote up and published the results of the expedition in the 12-volume *Denkmäler aus Ägypten und Äthiopien* (Lepsius, 1849–1856). Lepsius also brought myriad objects back for Berlin's Archaeological Museum, where he became curator and director in 1855.

At the request of the Church Missionary Society in London, Lepsius compiled a standard phonetic alphabet for linguistic transcription in 1855 (Lepsius, 1855, 1863). He transcribed 120 languages using the system he had developed, which became a fundamental tool for missionaries throughout Africa and beyond. Scholars such as Bantu expert Carl Meinhof applied his system to their work, as did missionaries such as Johannes Raum when he transcribed the East African Chagga language (Meinhof, 1899, 1910; Raum, 1909) (*see* **Meinhof, Carl Friedrich Michael (1857–1944)**). In 1864, Rhenish Society Missionary director Friedrich Fabri commented that his Society was consulting with Lepsius about the transcription of Southwest African languages (Fabri, letter to the British and Foreign Bible Society, Archives of the British and Foreign Bible Society, July 1864); and in 1867, J. L. Krapf went further, saying that most missionaries, Protestant and Catholic alike, were using Lepsius's orthography in their translations (Krapf, letter to the British and Foreign Bible Society, Archives of the British and Foreign Bible Society, April 1867). Later linguists and ethnologists deemed the system impractical, and it was ultimately superseded by the orthography that Diedrich Westermann and Ida Ward developed in the 1930s (Westermann and Ward, 1933; Mackert, 1999) (*see* **Westermann, Diedrich Hermann (1875–1956)**).

Late in his career, Lepsius published a book on Nubian grammar, which included an introduction about the people and languages of Africa (Lepsius, 1880). In this grammar, Lepsius attempted to classify the people and languages of the continent, and argued that the languages of Nubia were formed from a mixture of Bantu and Hamitic languages. Unlike Carl Meinhof, who stressed the primacy of light-skinned, culturally superior 'Hamites' from Europe or central Asia in the shaping of African languages, Lepsius declared that the oldest languages in Africa were first spoken by peoples living south of the equator. Like Meinhof, however, Lepsius believed that grammatical characteristics were more reliable for purposes of classification than were lexical ones, as grammatical features tended to remain more constant (Jungraithmayr, 1983).

Lepsius maintained missionary connections throughout his life, and was a devout Protestant who, shortly before his death in 1884, translated the Gospel of Saint Mark into Nubian. He had originally translated this Gospel for his Nubian grammar, in which it was included (Lepsius, 1880).

Leskien, August (1840–1916)

K R Jankowsky, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

August Leskien was born on July 8, 1840 in Kiel, a city in the northern part of Germany. He completed high school in 1860 and began university studies in his home town with the classical scholar Georg Curtius (*see* **Curtius, Georg (1820–1885)**). When Curtius left for Leipzig in 1862, Leskien went along. Apart from classical philology, he specialized in comparative philology. While still a student, he traveled to eastern European countries, where he became fascinated with southern Slavic languages. During semester breaks, he acquainted himself with Lower Sorbian by regularly visiting farmers in Spreewald in the Brandenburg province. In 1864, he obtained his doctorate and also passed the *Staatsexamen,* thus qualifying for teaching high school. For two years he taught Latin and Greek at the Thomas-Schule in Leipzig until, in 1866, he went to Jena to continue his academic studies under August Schleicher (*see* **Schleicher, August (1821–1868)**), with special emphasis on Baltic and Slavic languages. He received his final degree, *venia legendi* or habilitation, the formal initiation into the profession of a university teacher, in the field of comparative philology from the University of Göttingen in 1867 with the thesis *Futur und Aorist bei Homer.* He taught at Göttingen for two years, then accepted an appointment as associate professor *(Extra-Ordinarius)* in Jena, where he succeeded Schleicher. A year later, in 1870, he transferred to Leipzig as *Extra-Ordinarius* for Slavic philology. He became full professor *(Ordinarius)* there in 1876. During the following years, he declined numerous invitations from other German universities and preferred to stay in Leipzig, where he died on September 20, 1916.

Leskien occupied a special place in the Neogrammarian movement, which emerged around 1875. Directly or indirectly, he exerted a decisive influence on all principal participants in that he initiated the formation of the new philological methodology. When he published his *Declination im Slavisch-Litauischen und Germanischen* in 1876 (Leskien, 1876), he formally laid down the ground rules for what had already been practiced for quite some time by a large number of his friends and students: all historical language changes must either be reduced to the exceptionless operation of sound laws or be identified as the results of analogy. Leskien spoke for all Neogrammarians when he asserted that discarding the regularity principle would amount to admitting that language changes cannot be scientifically investigated at all.

Like all other Neogrammarians, Leskien was above all an extraordinarily productive scholar. At his time he was undisputed leader in his field of specialization, the Baltic–Slavic languages, and remained so for several generations, especially in the field of phonology. His work on syntax, amply documented as truly significant by his academic lectures held during the last years of his life, did not reach the stage of completion.

Leskien devoted most of his scholarly activities to the linguistic investigation of languages, but he was deeply interested also in all cultural aspects of language. His numerous publications on folk songs, fairy tales, and related literary topics, mostly dealing with Baltic and Slavic languages, were widely accepted as equal in quality to his linguistic works.

Leskien was quick in recognizing and acknowledging great talent in his own country as well as elsewhere. His speedy translation of William Dwight Whitney's (*see* **Whitney, William Dwight (1827–1894)**) *Life and growth of language* into German, only one year after its English original had appeared in 1875, is just one of many possible illustrations (Leskien, 1876).

Leskien's widely acknowledged achievements left their imprint not only on Baltic and Slavic studies, but also on historical and comparative linguistics in general. His works remain stimulating, and in some respects, indispensable.

Lesotho: Language Situation

N C Kula, Rijks Universiteit Leiden, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Lesotho, located in southern Africa, is completely surrounded by South Africa. The country covers an area of 30 355 km^2 and has a population of 1.8 million, based on 2003 United Nation estimates. Sesotho (or Southern Sotho) is the major language spoken in Lesotho; according to the *Ethnologue* (Grimes, 2003), the number of speakers is estimated to be 1.49 million people, which is approximately 85% of the population. This makes up about 37.5% of the total Sesotho-speaking population of southern Africa. Sesotho-speaking peoples have been in southern Africa since around 1400, after moving to this area from central parts of the continent. The Basotho nation emerged from the merger of a number of small Southern Sotho-speaking clans that King Moshoeshoe moved into the highlands of central South Africa at the beginning of the 19th century. Sesotho was the language of the Basotho people even before they settled in the region that is the current Lesotho, because the fleeing Nguni people that merged into the Basotho society were required to learn Sesotho. Sesotho was also the only official language of Lesotho up until its annexation by the British in 1868, at which time English was given official status. With independence in 1966, both Sesotho and English were made official languages by legislation. Today, Sesotho, with the majority of speakers, remains the national and official first language, with English as the official second language.

Despite being the official second language, English is quite prominent as the language of government, commerce, education, and the judicial system. In education, Sesotho is used as a medium of instruction from the ages of 6 to 9 years, after which it is taught as a subject in secondary school and may also be studied at the national university. Sesotho is also one of the earliest written African languages, with the first texts by French missionaries dating back to 1833. As a result, it currently boasts an extensive literature.

In addition to Sesotho and English, a few Nguni languages, particularly Zulu and Xhosa, are also spoken. This is not surprising, since apart from a large Southern Sotho-speaking area to the west and north of Lesotho, there are Zulu- and Xhosa-speaking peoples of South Africa to the east and south, respectively. Afrikaans is also spoken to some extent, in addition to various Indian and European languages.

Sesotho is classified in the Niger-Congo Bantu language phylum and is part of Guthrie's (1948) Zone S languages. Sesotho has some affinities with Tswana and Northern Sotho, which are spoken further north of Lesotho, although it must be noted that despite what the nomenclature may suggest, Northern Sotho (also called Sepedi) is linguistically closer to Tswana than it is to Sesotho (Southern Sotho).

Background Assumptions

Chomsky's earliest work (1957, 1959) stated the logical problem of language acquisition, or the poverty of the stimulus argument: the idea that given finite linguistic input, the speaker acquires the potential for infinite linguistic output. Furthermore, imperfect input arising from performance errors does not result in imperfect knowledge. According to Chomsky, it follows that the principles of grammar are underdetermined by the input, or primary linguistic data (PLD), and therefore the speaker must bring some innate linguistic knowledge or competence to the process of language acquisition. The idea that linguistic knowledge arises from "drawing out what is innate in the mind" (Chomsky, 1965: 51) is known by philosophers as the rationalist view, and contrasts with the empiricist view, which holds that linguistic knowledge is constructed on the basis of experience and is independent of any specialized cognitive system. The empiricist view is evident, for example, in the usage-based model of language acquisition favoured in cognitive linguistics (Langacker, 2000).

The model of the initial state of the innate language faculty posited by Chomsky is known as Universal Grammar and assumes a modular model of mind (see Chomsky, 1986: 13, 1986: 150; Fodor, 1983, 2000), according to which the language faculty represents an encapsulated system of specialized knowledge that equips the child for the acquisition of language. In developing this mentalist theory of language, Chomsky asserted that the only revealing object of linguistic study, given the objective of characterizing competence, is the system of linguistic knowledge in the mind of the idealized individual speaker. This system of internalized linguistic knowledge is known as I-language (Chomsky, 1986: 19–56) and generates the expressions uttered by the speaker. The theory of this system is referred to as the grammar, hence the term 'generative grammar.' From this perspective, the externalized language of the speech community (E-language) is merely epiphenomenal, in the sense that it arises as the output of individual I-languages. It is I-language that underlies the native speaker's intuitions concerning grammaticality. Central to this model is the grammatical transformation or displacement operation, which links two positions in a structure: the (thematic) position in which an expression is interpreted, and the position to which that expression has 'moved' in order to satisfy other grammatical requirements. For example, in (1), the fronted question word *who* is interpreted as the object of the verb *saw*; its thematic position is indicated by the underscore.

(1) Who did Lily say George saw_ yesterday?

Levels of Adequacy

Since Chomsky's early work (see, for example, 1965: 24–37), levels of adequacy have played a central role in the design of the generative model of language, which aims to characterize the linguistic knowledge or competence that underlies the individual speaker's I-language. According to Chomsky, an adequate theory of language must meet three criteria. The weakest of these criteria is observational adequacy, which is likely to be (at least partially) met by any grammar of any language. However, descriptive adequacy and explanatory adequacy are more stringent criteria that must be met by 'a genuine theory of human language' (Chomsky, 2000: 7). The three levels of adequacy can be summarized as follows.

Observational adequacy: The grammar of a particular language specifies which sentences are and are not well formed in that language. A grammar that is observationally adequate might contain statements such as 'This sentence is (un)grammatical in English' or 'These strings of words are sentences in English; these strings of words are not'. For example, an observationally adequate grammar of English would distinguish between (2a) and (2b), grammatical sentences, and (2c), an ungrammatical string.

(2a) Lily loves him
(2b) Lily loves herself
(2c) *Lily loves himself

Descriptive adequacy: The grammar of a particular language specifies which sentences are and are not well formed in that language *and* accounts for the speaker's intuitions concerning grammaticality by accurately modeling the tacit knowledge that underlies the (un)grammaticality of those strings and by describing their properties in terms of principles of language. A grammar that attains descriptive adequacy might contain statements such as 'This sentence is grammatical in English, and contains elements ABC, which stand in structural configurations PQR, and are governed by principles XYZ'. For example, a descriptively adequate grammar of English would account for the (un)grammaticality of the examples in (2) in terms of principles governing the distribution of pronouns like *him*, *himself*, and *herself* across the language as a whole. In Binding Theory (Chomsky,

1986: 164–184), these principles are stated in terms of coreference and locality. *Lily* can be coreferential with *herself*, since both expressions are third person, singular, and feminine; *Lily* is therefore a potential binder for *herself*, but not for *himself*, which explains why (2b) is grammatical while (2c) is not. Furthermore, reflexive pronouns like *herself* need to be bound locally: compare (2b) with (3a), where brackets indicate an embedded clause. In contrast, pronouns like *him* do not tolerate local binding. This explains why (2a) is grammatical (*Lily* cannot bind *him*), and why (3b) is only grammatical if *her* is not coreferential with *Lily*.

(3a) *Lily said [herself was hungry]
(3b) Lily loves her

Explanatory adequacy: The grammar provides a descriptively adequate account of each individual language *and* explains how knowledge of language is acquired via the interaction of the input (PLD) and the innate endowment (UG). A grammar that attains explanatory adequacy might contain statements such as 'This sentence is grammatical in English, and contains elements ABC, which stand in structural configurations PQR, and are governed by principles XYZ. These principles are represented as follows in UG and activated by exposure to PLD of the following kind...'. For example, an explanatorily adequate model of grammar would represent the binding principles described earlier in terms that are sufficiently general to account for the distribution of pronouns in all human languages, and sufficiently simple and economical to plausibly account for the acquisition of this knowledge on the part of the child, given exposure to everyday spoken language. In Binding Theory, the statement of principles capturing the distribution of both types of pronoun in (2) and (3) in terms of a single local binding domain represents an attempt to meet these objectives: while reflexive pronouns like *herself* must be bound within this domain, pronouns like *him* must not be bound within this domain.

Grammar of a Language versus a Theory of Language

As the previous section indicates, it is important to distinguish between a grammar of a particular language and a theory of human language (see Radford, 1988: 28–30). While the latter may be described as the ultimate objective of modern linguistic theory, it cannot be achieved in isolation from the former. In other words, a theory of human language that attains explanatory adequacy must contain the basis for a descriptively adequate account of each particular language. It has often been observed that there is a tension between the two objectives of descriptive and explanatory adequacy (see Chomsky, 1986: 51–52, 2000: 7, 2002: 31). While descriptive adequacy requires a large set of complex, intricate, and detailed statements in order to account for particular languages, explanatory adequacy requires a finite set of universal statements that can represent Universal Grammar in terms that are psychologically plausible. In particular, the goal of explanatory adequacy requires a small set of statements that are maximally general (in order to apply cross-linguistically) and maximally simple and economical (in order to account for the rapid and effortless acquisition of language, as well as for its creativity and the intuitions of its speakers). For example, as explained earlier, the principles of binding theory must account not only for speaker intuitions concerning grammaticality ('example [2c] is not a possible sentence in English') but also for speaker intuitions concerning possible interpretations of grammatical sentences ('in example [3b], *Lily* and *her* do not refer to the same person').

Role in the Development of the Model

We can trace a number of key developments in the Chomskyan model that represent attempts to resolve this tension between the objectives of descriptive and explanatory adequacy. For example, the move away from sets of constructions and construction-specific transformational rules to the single generalized transformational rule Move-alpha (Chomsky, 1980) represented a move toward explanatory adequacy. The development of the Principles and Parameters approach (Chomsky, 1981) also brought generative grammar closer to resolving the tension between the requirements of descriptive and explanatory adequacy, by positing the existence of a universal set of principles that account for Universal Grammar, together with a finite set of options or parameters that account for cross-linguistic variation.

Recent Developments

More recently, the development of the Minimalist Program (Chomsky, 1995) also represented a move toward the objective of explanatory adequacy, by reducing the grammar to two basic operations: 'Merge' (structure building) and 'Move' (displacement). Indeed, Chomsky argued that the Principles and Parameters approach was so successful in resolving the tension between the objectives of descriptive and explanatory adequacy that the Minimalist research agenda could go a step further. "In principle, then, we can seek a level of explanation deeper than

explanatory adequacy, asking not only *what* the properties of language are, but *why* they are that way" (Chomsky, 2001: 2). In pursuing this question, the Minimalist Program seeks to reexamine the principles of Universal Grammar from the perspective of questions about the design of the language system itself, rather than focusing primarily upon the design of the theory of language.

This article is reproduced from the previous edition, volume 4, pp. 2135–2136, © 1994, Elsevier Ltd.

Having graduated in law from the Paris Law Faculty and in philosophy from the Sorbonne in 1931, Lévi-Strauss visited Brazil in 1934. During a short spell teaching at the University of São Paulo he took the opportunity to do some fieldwork amongst Brazilian Indians. He returned to Brazil for another field trip in 1938–1939. He left France after the German occupation and went to New York where he taught at the New School for Social Research and met Roman Jakobson (*see* **Jakobson, Roman (1896–1982)**) whose work on phonology was to be one of his main intellectual inspirations. After the War he returned to Paris and held a post at the Musée de l'Homme and in 1950 became *directeur d'études* at the École Pratiques des Hautes Études. In 1959 the Chair of Social Anthropology was created for him at the Collège de France. In 1973 he became a member of the Académie Française. (He continues to publish at the time of writing, 1991.)

Lévi-Strauss is credited with creating the intellectual movement called 'structuralism.' The massive, technical, *Les Structures élémentaires de la parenté* was published in 1949 but perhaps nothing would have come of structuralism had Lévi-Strauss not published *Tristes tropiques* in 1955. This was a personal account of his travels, written in a readable, but sophisticated style, and it became a best-seller. That set the stage for the publication of *Anthropologie structurale* (*Structural anthropology*) in 1958 (a collection of essays written in the 1940s and 1950s). The popularity of the previous work guaranteed intense interest in this one. A new intellectual fashion had arrived. Structuralism replaced 'existentialism,' and Lévi-Strauss challenged Sartre's dominance as the star of Parisian intellectual life.

Lévi-Strauss declared that his three 'intellectual mistresses' were geology, psychoanalysis, and Marxism, the common idea being that in each of these enquiries what appears to be the case on the surface is determined by hidden (unconscious) structures, laws, or determinants. Among his other sources of inspiration were cybernetics, music, and above all linguistics.

The original structuralist charter is set out in Chapter 2 of *Structural anthropology*, originally

explanatory adequacy, asking not only *what* the properties of language are, but *why* they are that way" (Chomsky, 2001: 2). In pursuing this question, the Minimalist Program seeks to reexamine the principles of Universal Grammar from the perspective of questions about the design of the language system itself, rather than focusing primarily upon the design of the theory of language.

In 1959 the Chair of Social Anthropology was created for him at the Collège de France. In 1973 he became a member of the Académie Française. (He continues to publish at the time of writing, 1991.)

Lévi-Strauss is credited with creating the intellectual movement called 'structuralism.' The massive, technical, *Les Structures élémentaires de la parenté* was published in 1949 but perhaps nothing would have come of structuralism had Lévi-Strauss not published *Tristes tropiques* in 1955. This was a personal account of his travels, written in a readable, but sophisticated style, and it became a best-seller. That set the stage for the publication of *Anthropologie structurale* (*Structural anthropology*) in 1958 (a collection of essays written in the 1940s and 1950s). The popularity of the previous work guaranteed intense interest in this one. A new intellectual fashion had arrived. Structuralism replaced 'existentialism,' and Lévi-Strauss challenged Sartre's dominance as the star of Parisian intellectual life.

Lévi-Strauss declared that his three 'intellectual mistresses' were geology, psychoanalysis, and Marxism, the common idea being that in each of these enquiries what appears to be the case on the surface is determined by hidden (unconscious) structures, laws, or determinants. Among his other sources of inspiration were cybernetics, music, and above all linguistics.

The original structuralist charter is set out in Chapter 2 of *Structural anthropology*, originally

published as an article in 1945 in one of the first issues of *Word*. Structural linguistics, through Trubetzkoy's phonology (*see* **Trubetskoy, Nikolai Sergeievich, Prince (1890–1938)**), was set to play a 'renovating role' in the social sciences. Edwin Ardener has pointed out that the specialized terminology of phonemic analysis was a red herring. It was the Saussurian principles (*see also* **Saussure, Ferdinand (-Mongin) de (1857–1913)**) lying behind phonology that Lévi-Strauss required: a few simple distinctions (like langue/parole, syntagmatic/paradigmatic), related notions such as 'system' and 'value,' and above all, the idea that the building blocks of human logic and human thinking consist of binary oppositions.

The guiding idea behind Lévi-Strauss's work was to find fundamental structures behind the bewildering disparateness of phenomena. *Elementary structures* was an attempt to show that a huge array of kinship systems could be seen to be based on two simple structural forms: restricted exchange and generalized exchange. From *Totemism* onward the search is more explicitly for fundamental structures '*of the mind*,' the idea being that by an examination of the structure of various 'objects of thought' (classifications, myths, designs) one can discover something of the structure of the mind that created them. Just as phonology had shown that language can be reduced to those 'distinctive features' expressed as binary distinctions (tense/lax, grave/acute), so the logic of primitive classification and 'mythologic' can be reduced to endless structures of binary oppositions (wet/dry, honey/tobacco, raw/cooked).

While Lévi-Strauss emphasizes his profound concern with linguistics, Chomsky's generative grammar passed him by. ('Transformation,' a key term in structuralism, is taken from D'Arcy Wentworth Thompson's *On growth and form*, 1917, a classic in zoology, and has nothing to do with transformational grammar.) Ironically, a short passage in Chomsky's *Language and mind* provides an illuminating, terse, 'no nonsense' critique of Lévi-Strauss's use of linguistic models. (The work on classification, says Chomsky, reduces to the conclusion "that humans classify, if they perform any mental acts at all.") Linguistics has long left Lévi-Strauss behind. Structuralism, as a fashion, also looks rather dated, but because of the engrossing nature of the material Lévi-Strauss deals with (myths, masks, exotic names and habits) his writing is still found intriguing, and he is still revered as one of the leading *intellectuels* of France.

Levita, Elijah (1469–1549)

H Y Sheynin, Gratz College, Melrose Park, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Elijah Levita (1469–1549) is known in Jewish scholarship as Eliyyāhū Bāḥūr, an outstanding Hebrew and Aramaic grammarian and lexicographer, Rabbinic scholar, and Yiddish writer. A native of Neustadt, near Nuremberg, Germany, he lived mostly in Italy (Padua, Venice, and Rome) and died in Venice.

Levita's main achievement was the instruction of Christian scholars in Jewish linguistic teachings. Some of his pupils were his patrons, in whose homes he resided for long time. Among his disciples were

scholars who became the leading Hebrew linguists of the 16th century, such as Sebastian Münster, Paulus Fagius, Jean de Campen (Campensis), Andreas Maes, Guillaume Postel, Johann Albrecht Widmanstetter (Widmanstadius), Georges de Selves, and Cardinal Egidio di Viterbo, with whom Levita stayed for 13 years.

Levita, who wrote in Hebrew, published many Hebrew grammar works, Hebrew and Aramaic dictionaries, and masoretic treatises. The most important in chronological order are: his edition of Moses Qimhi's short grammar *Mahălakh Šĕvīlē ha-Da'at* ('Course of paths to the knowledge') with his own commentary (Pesaro, 1508), his notes ('Nimmūqīm') on David Qimhi's grammar *Séfer ha Mikhlōl*, ('Book of perfection') and dictionary *Sēfer ha Šŏrāšīm* ('Book of roots'), published only partially in his editions of David Qimhi's works.

Two of his own grammatical treatises were first printed in Rome in 1518–1519 and almost simultaneously translated into Latin by his pupil Sebastian Münster. These were *Sēfer ha-Harkāvāh* ('The book of construction,' Rome, 1518) and *Sēfer ha Baḥūr* ('The book of the chosen,' Rome, 1518); while the third one, *Lu'aḥ bĕ-diqdūq ha-Pe'ālīm wehabinyānīm* ('The tables of the grammar of the verbs and the formations') remained unpublished. The first one of these books analyzed foreign and compound words in the bible, and the morphology of the noun and the verb; the second was a more general book on Hebrew that was retitled, starting with its second edition as (Isny, 1542) *Diqdūq Eliyyāhu ha-Lēwī* ('Eliyyāhū ha-Lēwī's grammar'). His minor work, *Pirqē Eliyyāhū* ('Elija's chapters,' Pesaro, 1520) dealt with Hebrew consonants and vowels; in the 2nd edition (Venice, 1546), there were additions regarding nouns' templates (*mishqālim*) and the auxiliary letters used in construction of the noun (roughly coincide with affixes).

Levita devoted at least two of his works to masoretic research, *Māsōret ha-Māsōret* ('The tradition of the Māsōrāh,' Venice, 1538), in which he explained the symbols and the terminology of the ancient transmission of the biblical text and *Ṭūv Ṭa'am* ('The correctness of the accent'), where he attempted to formulate rules for use of accents in the bible.

Levita went beyond the study of biblical Hebrew, an unprecedented move compared to previous linguistic tradition. His lexicographic work *Tishbī* ('The Tishbite') listed words selected from the Talmud and other rabbinic sources; his *Mĕturgĕmān* ('The interpreter,' Isny, 1541), analyzed the Aramaic lexics of the *Targūmīm* (Aramaic versions of the Hebrew bible). The last is still instrumental for Aramaic research; his *Sēfer ha-zikhrōnōt* ('Book of the mentions') was reportedly the first concordance to the bible (still in manuscripts).

Levita's pioneer work on Old Western Yiddish, or Judeo–German language, *Shĕmōt dĕvārīm* ('Names of things,' Isny, 1542) was the first Yiddish–Hebrew dictionary.

Levita is largely responsible for the development of the linguistic study of Hebrew in Europe, falling in line with David Qimḥi's teachings, which Levita adopted as a model for his research.

Lévy-Bruhl, Lucien (1857–1939)

S O'Neill, University of Oklahoma, Norman, OK, USA

© 2006 Elsevier Ltd. All rights reserved.

Lucien Lévy-Bruhl was born in Paris, France, on April 10, 1857. There he attended the École normale supérieure, receiving a broad education in philosophy, music, natural science, and clinical psychology, before graduating in 1879. After earning a doctorate in philosophy at University of Paris, in 1896 Lévy-Bruhl accepted a professorship at Sorbonne's Department of Modern Philosophy, where he later served as chair, starting in 1904.

A chance encounter with Chinese philosophy early in his career first prompted him to explore non-Western modes of thought, beginning an intellectual adventure that he continued until his death in 1939. Lévy-Bruhl saw the emerging literature on non-Western societies – though virtually unknown to previous generations of philosophers – as a promising testing ground for exploring the scope of human thought. Based on his extensive readings of the many ethnographic reports available at the time, Lévy-Bruhl began to build a second career as an anthropologist, later helping to found the Institute of Ethnology at the Sorbonne in 1925, with noted anthropologists Paul Rivet and Marcel Mauss. Yet after a falling-out with the eminent sociologist Émile Durkheim, Lévy-Bruhl left the Sorbonne in 1927, never to return. For the next decade, he continued his research on non-Western thought processes while delivering a series of popular though controversial lectures at Harvard, Berkeley, Columbia, and Johns Hopkins, to name a just few of the great universities where he presented his ideas. Lévy-Bruhl died in Paris on March 13, 1939, heartbroken about the coming war.

Lévy-Bruhl is best known for his bold speculations on cognition in preliterate societies, something he initially characterized as "primitive mentality" or even "prelogical thought," before uncovering similar trends in Western societies. As a student of Greek philosophy, Lévy-Bruhl was struck by what he characterized as non-Aristotelian nature of the thought processes found in such widespread phenomena as magical practices and totemism, or the belief in unseen spiritual forces. For none of these phenomena could be directly verified with the senses, nor were they generally amenable to logical proof or contradiction. When a magical spell failed to produce its result, another unseen force was blamed. When a family claimed descent from an animal or a plant, the premise was accepted through the force of tradition and emotional attachment, not empiricism or reason. Lévy-Bruhl's awareness that all humans apply logical principles to some endeavors, such as economics, only brought the absence of so-called rational thought into greater relief, where it lay dormant.

Bent on illustrating the lesser development of non-Western societies, Lévy-Bruhl quickly uncovered evidence of 'primitive mentality' in the sphere of language, which he reported in his first major work, *How natives think*, first published in 1910. Most notably, Lévy-Bruhl stumbled on reports that numerals are limited in some languages, often with numbers going no higher than two, three, or four. Yet, to his credit, Lévy-Bruhl was quick to note that the absence of higher numerals does not preclude the possibility of counting, which he regarded as a human universal, available to all through addition, multiplication, or tallies, even where the set of numbers is small. He simply argued that numbers remained undeveloped where there is little use for counting, with language following the mental habits, though not the potential ability, of the speakers.

Upon discovering that some languages have special grammatical markers for just two, three, or four objects, Lévy-Bruhl claimed these languages failed to develop the far more abstract category of the plural that is common in the West. Instead, he claimed those languages cling to the more 'concrete' concepts of the dual, trial, or quintal where an exact number must be specified. He made a similar argument about classifier languages, arguing that a concrete shape must always be stated, at the expense of developing a more 'abstract' concept of number, apart from the

Lucien Lévy-Bruhl was born in Paris, France, on April 10, 1857. There he attended the École normale supérieure, receiving a broad education in philosophy, music, natural science, and clinical psychology, before graduating in 1879. After earning a doctorate in philosophy at University of Paris, in 1896 Lévy-Bruhl accepted a professorship at Sorbonne's Department of Modern Philosophy, where he later served as chair, starting in 1904.

A chance encounter with Chinese philosophy early in his career first prompted him to explore non-Western modes of thought, beginning an intellectual adventure that he continued until his death in 1939. Lévy-Bruhl saw the emerging literature on non-Western societies – though virtually unknown to previous generations of philosophers – as a promising testing ground for exploring the scope of human thought. Based on his extensive readings of the many ethnographic reports available at the time, Lévy-Bruhl began to build a second career as an anthropologist, later helping to found the Institute of Ethnology at the Sorbonne in 1925, with noted anthropologists Paul Rivet and Marcel Mauss. Yet after a falling-out with the eminent sociologist Émile Durkheim, Lévy-Bruhl left the Sorbonne in 1927, never to return. For the next decade, he continued his research on non-Western thought processes while delivering a series of popular though controversial lectures at Harvard, Berkeley, Columbia, and Johns Hopkins, to name a just few of the great universities where he presented his ideas. Lévy-Bruhl died in Paris on March 13, 1939, heartbroken about the coming war.

Lévy-Bruhl is best known for his bold speculations on cognition in preliterate societies, something he initially characterized as "primitive mentality" or even "prelogical thought," before uncovering similar trends in Western societies. As a student of Greek philosophy, Lévy-Bruhl was struck by what he characterized as non-Aristotelian nature of the thought processes found in such widespread phenomena as magical practices and totemism, or the belief in unseen spiritual forces. For none of these phenomena could be directly verified with the senses, nor were they generally amenable to logical proof or contradiction. When a magical spell failed to produce its result, another unseen force was blamed. When a family claimed descent from an animal or a plant, the premise was accepted through the force of tradition and emotional attachment, not empiricism or reason. Lévy-Bruhl's awareness that all humans apply logical principles to some endeavors, such as economics, only brought the absence of so-called rational thought into greater relief, where it lay dormant.

Bent on illustrating the lesser development of non-Western societies, Lévy-Bruhl quickly uncovered evidence of 'primitive mentality' in the sphere of language, which he reported in his first major work, *How natives think*, first published in 1910. Most notably, Lévy-Bruhl stumbled on reports that numerals are limited in some languages, often with numbers going no higher than two, three, or four. Yet, to his credit, Lévy-Bruhl was quick to note that the absence of higher numerals does not preclude the possibility of counting, which he regarded as a human universal, available to all through addition, multiplication, or tallies, even where the set of numbers is small. He simply argued that numbers remained undeveloped where there is little use for counting, with language following the mental habits, though not the potential ability, of the speakers.

Upon discovering that some languages have special grammatical markers for just two, three, or four objects, Lévy-Bruhl claimed these languages failed to develop the far more abstract category of the plural that is common in the West. Instead, he claimed those languages cling to the more 'concrete' concepts of the dual, trial, or quintal where an exact number must be specified. He made a similar argument about classifier languages, arguing that a concrete shape must always be stated, at the expense of developing a more 'abstract' concept of number, apart from the

actual objects being counted. Of course, his Boasian contemporaries in the United States argued that ranking languages is a futile endeavor, like comparing apples and oranges, because all languages are complex in some areas and less so in others. At the other extreme, Benjamin Lee Whorf took cases like classifiers or the grammatical dual as evidence of great cognitive sophistication on the linguistic plane.

Surveying the literature on the languages of North America, Lévy-Bruhl encountered several detailed accounts of polysynthetic tongues, which he described as "pictorial" because of the high number of grammatical affixes that must modify the stem. Again, rather than portraying these languages as sophisticated, he charged the speakers of polysynthetic languages with requiring the painstaking specification of so many 'concrete' categories, indicating, for instance, the shape of an object as it moves through space, its precise directional bearing, or its placement at an exact moment in the near or distant future. At the same time, Lévy-Bruhl noted that many languages have a profusion of words for individual species, often far exceeding the common terms available in European tongues while lacking a detailed series of generic categories for general classes of plants and animals. Again, instead of crediting indigenous languages with sophistication in some areas, Lévy-Bruhl selectively focused on the area in which a language appeared to be deficient from the perspective of English or French. By the same token, English, French, or German could also be regarded as equally deficient, with a paucity of grammatical affixes or precise names for the many animal species found remote parts of the world!

Late in his life, Lévy-Bruhl eventually answered his critics, acknowledging that similar processes were at work in Western societies, a revelation that came only with the posthumous publication of his private notebooks in 1949. For even such a cherished doctrine as the Holy Trinity to some extent defies rational thought, with its assertion that one God is simultaneously present in three species as the Father, the Son, and the Holy Spirit. Like the concept of the totem, the proposition is beyond empirical proof and must be accepted on faith, emotion, and tradition, or not at all. Similarly, magical thinking was prevalent until recently, and though it is mostly gone, luck and prayer survive. No longer able to maintain the sharp distinction between Western and non-Western societies, Lévy-Bruhl recognized two streams of thought found in all societies, one 'rational' and another one 'prelogical' or 'mystical.' By collapsing the two-way split between the Western and non-Western worlds, he paved the way for his intellectual successor, Claude Levi-Strauss, who continued to explore the scope of human thought, though with emphasis on purely universal process, manifest in various ways across a range of societies.

Lewis, Henry (1889–1968)

B F Roberts, Ceredigion, UK

© 2006 Elsevier Ltd. All rights reserved.

As one of the first generation of professors of Welsh at the University of Wales, Henry Lewis, like his colleagues, was called upon to prepare editions of and commentaries on a wide range of texts as well as writing numerous lexicographical notes, but from the early years of his career he made the study of Welsh syntax and comparative grammar the cornerstones of his own pioneering research. He became the foremost Welsh comparativist and grammarian of the first half of the 20th century.

Born on August 21, 1889 in Ynystawe in the Swansea Valley in Glamorganshire, south Wales, Henry Lewis was educated at his local county school at Ystalyfera, where he received a sound classical education and was fortunate in also having a scholarly and inspiring Welsh teacher who attracted him to Welsh studies. In 1907 he entered the University College of South Wales at Cardiff, where he studied under Thomas Powel, taking his degree in Welsh in 1910. Lewis gained his research degree in 1913 for work on the Welsh translations of Geoffrey of Monmouth's *Historia Regum Britanniae,* and he also spent a period at Jesus College, Oxford, with Sir John Rhys, professor of Celtic; though he did not take a degree, one can assume that Rhys would have broadened his outlook toward the wider field of Celtic studies. Following a period of school teaching and war service, Lewis was appointed assistant lecturer in Welsh at Cardiff, where he remained from 1918 to 1921. The university college of Swansea, another constituent college of the University of Wales, was opened in 1920; the following year Henry Lewis took up his post as the first professor of Welsh. He was to remain there until his retirement in 1954. He died on January 14, 1968.

At Swansea, Lewis had the responsibility of establishing a university department from scratch and teaching a full initial degree program with the help of one, sometimes two, lecturers. He was also actively involved in the broader Welsh cultural scene as a member of official bodies and institutions and as a popular extramural teacher, educationalist, and convinced Congregationalist. These activities and the different facets of his teaching are reflected in the range of his publications, from Early Modern Welsh translations and renaissance prose, to editions of 18th and 19th century minor classics and school and church texts. One of Lewis's main contributions, however, was his editions of medieval prose and poetry. His studies of *cywyddwyr*, poets of the 15th and 16th centuries, especially in a joint work, *Cywyddau Iolo Goch ac eraill* (The *cywyddau* of Iolo Goch and others, 1925, 1937) helped to establish modern scholarly editorial conventions for this body of verse. More innovative was his work on the poets of the Welsh princes of the 12th and 13th centuries; his *Hen gerddi crefyddol* (Old religious verse, 1931) was the first modern edition of any of the poems of these poets, and his annotations helped to lay the foundations for later studies of metrics, style, and lexicon.

In 1942 Lewis returned to the subject of his early research. *Brut Dingestow* is an edition of a single manuscript translation of Geoffrey of Monmouth. His analysis of some of the grammatical features of this 13th century text, the culmination of work begun in other editions of medieval prose texts, *Chwedleu seith doethon Rufein* (The seven sages of Rome, 1924) and *Delw y byd, Imago mundi* (with Paul Diveres, 1928), is an extended, though never intended as a comprehensive, grammar of Middle Welsh. His *Elfen Ladin yn yr iaith Gymraeg* (The Latin element in Welsh, 1943) remains a useful handbook for plotting the phonological changes from British to Welsh, while his deep knowledge of British Celtic languages enabled him to make a significant contribution in the examination of their phonology and morphology in the revised English edition of Holger Pedersen's *Vergleichende Grammatik der Keltischen Sprachen* (*A concise comparative Celtic grammar*, 1937; Russian translation in 1954, with Lewis's further corrections and a supplement in 1961). Lewis had begun to publish grammars of Middle Breton and Middle Cornish in 1922 and 1923 (revised editions in 1935, 1946; new edition with J. R. F. Piette in 1966; German editions in 1990), and there is no doubt that it was he who paved the way for these languages to become an integral part of Celtic linguistics in Wales and beyond. Lewis's other major, and probably more important, achievement in Welsh scholarship was to make syntactical analysis central to Welsh linguistics. His work on Old Welsh syntax, prepositions, the syntax of the verb and of relative clauses, and especially his description and proposed history of the syntax of the unmarked noun-initial sentence, set out in his 1942 British Academy Lecture, 'The sentence in Welsh,' have been very influential (though it has to be said that this thesis has been criticized in recent years). Lewis was an inspiring teacher, some of whose students have become leading Welsh grammarians; he was a fluent communicator, and his *Datblygiad yr iaith Gymraeg* (The development of the Welsh language, 1931, revised in 1946, German edition in 1989), written for non-academic readers, is still a scholarly, readable account of language development.

Lexeme–Morpheme Based Morphology

R Beard, Bucknell University, Lewisburg, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Lexeme–Morpheme Based Morphology is a complete set of lexeme-based morphological theories and hypotheses including the following:

1. The Separation Hypothesis, that lexical and inflectional derivation are distinct from affixation (phonological realization);
2. The Universal Grammatical Function Theory, whereby the functions of inflectional and lexical derivation are one and the same;
3. The Base Rule Hypothesis, that universal functions must originate in a base component if we are to explain both lexical and syntactic (inflectional) derivation (Botha, 1988);
4. Stephen Anderson's General Theory of Affixation (Anderson, 1992), which, as extended recently by Anderson, predicts the placement of all affixes and clitics;
5. The Defective Adjective Hypothesis, which claims that adpositions are adjectival pronouns in a class with case endings and hence grammatical morphemes rather than lexemes.
6. A morphological performance theory, which includes: a theory of lexical stock expansion processes; a theory of normal speech errors; a theory of pathological speech errors (morphological agrammatism).

The LMBM lexicon is exclusively the domain of lexemes, which are defined specifically as noun, verb, and adjective stems and the lexical categories that define them (number, gender, transitivity, and so on). All other meaningful material must belong to the closed set of closed categories of grammar and are handled by 'morphology' in the general sense (derivation plus affixation). LMBM, then, distinguishes itself from other lexeme-based theories in that it maintains a pristine distinction between lexemes and grammatical morphemes and consequently predicts this distinction at every level of language and speech.

Lexemes and Morphemes

Lexeme-Morpheme Based Morphology (LMBM) is a variant of what Aronoff (1994) refers to as a 'lexeme-base' morphological theory. Lexeme-base morphology assumes that only the lexeme is a true linguistic sign, where 'lexeme' is defined exclusively and explicitly as any and all noun, verb, and adjective stems. The effects of lexical and inflectional

Lexeme–Morpheme Based Morphology

R Beard, Bucknell University, Lewisburg, PA, USA

Introduction

Lexeme–Morpheme Based Morphology is a complete set of lexeme-based morphological theories and hypotheses including the following:

1. The Separation Hypothesis, that lexical and inflectional derivation are distinct from affixation (phonological realization);
2. The Universal Grammatical Function Theory, whereby the functions of inflectional and lexical derivation are one and the same;
3. The Base Rule Hypothesis, that universal functions must originate in a base component if we are to explain both lexical and syntactic (inflectional) derivation (Botha, 1988);
4. Stephen Anderson's General Theory of Affixation (Anderson, 1992), which, as extended recently by Anderson, predicts the placement of all affixes and clitics;
5. The Defective Adjective Hypothesis, which claims that adpositions are adjectival pronouns in a class with case endings and hence grammatical morphemes rather than lexemes.
6. A morphological performance theory, which includes: a theory of lexical stock expansion processes; a theory of normal speech errors; a theory of pathological speech errors (morphological agrammatism).

The LMBM lexicon is exclusively the domain of lexemes, which are defined specifically as noun, verb, and adjective stems and the lexical categories that define them (number, gender, transitivity, and so on). All other meaningful material must belong to the closed set of closed categories of grammar and are handled by 'morphology' in the general sense (derivation plus affixation). LMBM, then, distinguishes itself from other lexeme-based theories in that it maintains a pristine distinction between lexemes and grammatical morphemes and consequently predicts this distinction at every level of language and speech.

Lexemes and Morphemes

Lexeme-Morpheme Based Morphology (LMBM) is a variant of what Aronoff (1994) refers to as a 'lexeme-base' morphological theory. Lexeme-base morphology assumes that only the lexeme is a true linguistic sign, where 'lexeme' is defined exclusively and explicitly as any and all noun, verb, and adjective stems. The effects of lexical and inflectional

derivation on the lexeme do not affect its status as a sign at all. These processes, it follows, must involve elements other than linguistic signs.

Lexical (derivational) and inflectional morphemes hence must represent different types of linguistic elements. The fundamental claim distinguishing LMBM from other morphological frameworks is its rigid distinction of lexemes and (grammatical) morphemes; hence its name, 'Lexeme–Morpheme Based Morphology.' Beard (1988, 1995) argues that grammatical morphemes differ from lexemes in the following ways:

1. lexemes belong to open classes; morphemes belong to closed classes.
2. lexemes do not allow zero or empty forms; morphemes do.
3. lexemes have extragrammatical referents; morphemes have grammatical functions.
4. lexemes may undergo lexical derivation; morphemes may not.
5. lexemes are not paradigmatic; morphemes are.

The Separation Hypothesis

If lexemes are noun, verb, and adjective stems, and if they are the only objects stored in the lexicon, it is natural to ask what determines or generates grammatical morphemes. Grammatical morphemes are the output of purely phonological operations independent of the semantic (grammatical) operations they mark ('realize'). This conclusion is the Separation Hypothesis.

The Separation Hypothesis splits all derivation, lexical and inflectional alike, into three processes: lexical (L-) derivation, inflectional (I-) derivation, and morphological spelling. Derivation involves operations on abstract lexical and inflectional category functions such as [+Plural, -Singular], [+Past, -Present], [+1st], and the like. Spelling is the purely phonological realization of the morphological categories of any base lexeme that has undergone such derivation. Its function is to distinguish stems that have undergone derivation from those that have not. If the derivation is inflectional, the marker may be attached to the lexical stem or assigned independently to a structural position in syntax in ways which syntax alone cannot predict. For example, [+Definite] singular nouns in Swedish are suffixed, but [-Definite] singular nouns are marked by the same morpheme in a free position, e.g., *en katt* 'a cat' vs. *katt-en* 'the cat.' Hence, the LMBM lexicon contains neither bound nor free grammatical morphemes – both are the responsibility of morphological spelling.

'Morphemes'

What, then, are 'morphemes' under this hypothesis? Bound morphemes include affixes and other modifications of the phonological representation of a lexeme, such as reduplication and (Semitic) revoweling, the spelling out of articles, auxiliaries, adpositions – any expression associated with a grammatical category or relation rather than a semantic one.

Under LMBM, L-derivation takes place in the lexicon. Here, lexemes with new lexical meanings are formed from underived lexemes. Inflectional derivation, following the arguments of Matthews (1972), Anderson (1992), and Aronoff (1994), takes place in syntax. Both these derivational types are phonologically realized by an autonomous morphological spelling component located after all syntactic rules but before any phonological rules operate.

Unlike free morphemes, then, bound morphemes are phonological modifications (only) of the phonological representations of lexemes, which mark the fact that the lexeme has undergone lexical or inflectional derivation (the Empty Morpheme Entailment). Neither type of morpheme has any meaning, and thus morphemes attribute no meaning to the stems to which they attach. All meaning is accounted for by the derivation rules. This immediately explains empty and zero morphemes. Empty morphemes represent affixation without derivation; zero morphemes are derivations without affixation. Morphological asymmetry, the many-to-one and one-to-many mappings of morphological forms to function, is also explained by Separation.

Free morphemes, on the other hand, may require syntactic positions, since they are ostensibly subject to movement and also often belong to paradigms. I have in mind now such morphemes as free adpositions, auxiliaries, conjunctions, and pronouns. All but conjunctions are themselves subject to inflection. Pronouns such as *which* and *who*, as well as free auxiliaries, seem to move from one syntactic position to another in some languages. However, even the positions of auxiliaries and pronouns usually conform to Anderson's General Theory of Affixation, which LMBM also assumes. Moreover, movement may simply be the phonological realization of grammatical morphemes in positions other than that in which the morphological features determining such realization appear (Beard, 1995).

Lexical Derivation

Derivation rules operate in the lexicon (L-derivation) and in syntax (I-derivation). The illusion of a direct relation between the sound and meaning of affixes is the result of two facts. First, derivation rules and

realization rules operate on the same lexeme during the generation of a derived word. This means that affixation will correspond to the modified features in the stem. (The original features of the stem will also be modified, neutralized, so that they will not trigger affixation.)

The order of affixes generally, but not always, follows that of the features in the base. The assumption of sign base morphology (Saussure, 1916) results from the fact that the default procedure for the MS (spelling) component is to realize features in the order in which it encounters them. However, feature order is often irrelevant, as in the case of affixes, which can precede or follow some other affix, and cumulative exponents, which realize two or more features simultaneously.

Beard (1988, 1995) describes four types of L-derivation: transpositions, functional derivation, feature switches, and expressive derivation. Transposition simply changes the lexical class (category) of a lexeme, e.g., N to V, A to N. Functional derivations add a semantic(ally interpretable) category function, such as Subject, Object, Locus, Manner, to the featural inventory of the base lexeme. Lexical switches modify the value of inherent lexical features such as Gender, Number, and Paradigm Class. Finally, expressive derivations, such as Diminutive and Augmentative, reflect the speaker's attitude in ways still not clearly understood.

The Subjective (Agentive) nominalization, e.g., 'bake : baker,' is a familiar L-derivation. It invokes three of the four L-derivation types, a functional derivation illustrated in Figures 1–3, a transposition, whose output is as seen in Figure 3, and a featural switch, whose output is illustrated in Figure 4.

Figure 1 is a simplified illustration of the underlying form of an NP with a relative clause, the origin of all nominalizations under LMBM. The problem is that for all the structure, only one phonologically realizable lexeme has been inserted. The lexicon has two options: remove the structure and nominalize the verb, or fill in the structure with lexical categories it knows and controls (Gender, Number, and Noun Class).

If the lexicon chooses the former tack, the superfluous structure marked in Figure 1 is eliminated (Figure 2). The result is a single V incorrectly positioned under an NP. When this occurs, the lexicon's job is to transpose the illegal category to the legal one, i.e., provide the verb with nominal category functions (Figure 3). Figure 3 also shows the effects of the feature switches, which sets the functional features added by the transpositions. The output of this series of processes is then submitted to morphological spelling (the MS-module), similar to 'Spellout' in related models. Of course, the lexical description of the verb *bake*, {BAKE}, is preserved in the derivation and will continue to determine government and binding properties.

This set of assumptions accounts for the following facts. Languages with L-derivation have exactly two ways of expressing the same notion using identical lexemes: one lexical (bak-er), the other syntactic (someone who bakes). The same functions (Subject, Object, Instrument, Location) found among Case relations also determine functional L-derivations. Although there are two types of derivations, lexical and inflectional, only one spelling component realizes the results of both.

Figure 1 A functional derivation.

Figure 2 Input to a transposition.

Figure 3 Output of a transposition.

Figure 4 Output of a featural switch.

Now that we have followed a lexical derivation, let us examine an inflectional one operating on the same underlying form as in Figure 1.

Inflectional Derivation

If the lexicon decides not to operate on a structure such as that in Figure 1 above and does not collapse all that structure into a single word, it must license all the nodes that pass through it for syntax; that is, it must assure that all NPs are headed by acceptable Ns, all VPs by Vs, all APs by As. This is apparently the role of pronominals. Pronominals are also tightly constrained by LMBM: categorically, they may contain only those lexical categories determined by the lexicon, the inflectional categories found in syntax. No other type of semantic or grammatical category may be found in a pronominal (proadjective, pronoun, proverb). That is, for example, pronouns may be completely described in terms of Number, Gender, Lexical Category, etc. However, the processes of transposition and feature switching provide precisely the categories demanded by the empty nodes in Figure 1, and these categories are necessary and sufficient conditions on the semantic interpretations of pronominals.

If no L-derivation applies to the example in Figure 1, it will be provided with the lexical categories of Gender, Noun Class, and Number from the lexicon. (Animacy is derivable from Natural Gender; see Beard, 1995.) If no L-derivation applies to the example in Figure 1, these pure lexical categories, along with the inflectional categories of the Subject NP, will be raised to C by wh-movement, and the output of (1) from syntax will be, roughly, the structure illustrated in Figure 4.

Syntactic structures like the example in Figure 4, as well as lexically derived structures as in Figure 3, are then subjected to the phonological realization rules of the morphological spelling or MS component. LMBM postulates only one integrated MS component for both lexical and inflectional derivations. Pronouns such as *one*, *he*, *she*, *it*, being grammatical morphemes, will be phonologically realized by the same MS component that inserts affixes.

Morphological Spelling (Realization)

Morphological spelling (MS) comprises the phonological realization rules of morphology. These are rules that determine the modification of lexical stems, if any, conditioned by the presence of derivational features. The MS module can read any features of a lexeme but can modify only the phonological (P) representation. It must contain a short-term memory component that can hold several features before writing to the P-representation of the lexeme. This accounts for the fact that a single affix can represent several grammatical features. MS memory will have to collect the features [+Active], [+Indicative], [+1st], and [+Singular] before it can attach the /o/ to the Latin stem *am-* in order to generate *amo* 'I love.' This same capacity allows the MS component to reorder affixes, such as in Turkish *gelir-ler-se* and *gelir-se-ler*, both of which mean 'if they come.'

Realizations of the pronoun *one*, i.e., *someone, anyone, the one(s)*, result from accumulations of lexical features like [± Masculine], [± Plural] with syntactic features like [± Specific] and [± Definite] inserted into empty nodes that are not allowed by English grammar. The MS-module interprets both the lexical and inflectional features of the ultimate nodes and realizes them as pronouns, i.e., *the one/someone who bake-s*.

Lexeme representations obviously comprise a phonological, a grammatical, and a semantic representation. The MS-module must be able to read all three representations but can modify only P, given its purely phonological nature. In fact, this is the function of morphology, which is the interface between the lexicon and syntax, on the one hand, and the phonological or sign output, on the other.

Conclusion

This brief introduction to LMBM has outlined the basic assumptions about (1) the lexicon, (2) lexical derivation rules, (3) inflectional derivation rules, and (4) morphological realization. The full theory is available in Beard (1995). Beard (1981, 1987)

provides a general theory of morphological performance that distinguishes most types of extragrammatical derivational processes from those determined by grammar.

Lexical Acquisition

D McCarthy, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Lexical acquisition is the production or augmentation of a lexicon for a natural language processing (NLP) system. The resultant lexicon is a resource like a computerized dictionary or thesaurus but in a format for machines rather than people. The entries in a lexicon are lexemes, and the information acquired for these includes the forms, meanings, collocations, and associated statistics.

Acquisition is vital for NLP because the performance of any system that processes text or speech is dependent on its knowledge of the vocabulary of the language being processed. As well as an extensive grasp of the vocabulary, a system needs a means to cope when it encounters a word that it has not seen before. Because of the requirements of an application, there may be a case for limiting a system to the words appropriate within a specific domain. However, even in a specific domain, everyday words will be used and there will be additional domain-specific terminology. It is possible, and sometimes appropriate, to build a system that can run using only a small vocabulary. However, it is nevertheless necessary to acquire appropriate forms and meanings of the lexemes for the given domain. The lexical information required is not explicitly listed in any available resource, and getting humans to provide it is extremely costly. For this reason lexical acquisition is frequently referred to as the bottleneck for NLP. In order to produce lexicons for deployable NLP systems, lexical acquisition must be automated.

There are significant differences between the requirements of a lexicon intended for a computer system and the contents of a dictionary or thesaurus written for humans. Machine-readable dictionaries and thesauruses (MRDs and MRTs) have been designed for online use by humans. If the information contained were sufficient then one could permit a NLP system to use them directly, or after some simple reformatting. However, while it was hoped that machine-readable resources produced by humans for humans would be a viable means of populating lexicons, it is now widely recognized that this method will not work. The resources are prone to omissions, errors, and inconsistencies. Furthermore, the lexicographers producing these resources rely on the fact that users have an adequate grasp of the language, knowledge of the world, and basic intelligence to understand the definitions supplied and fill in any gaps. For example, a human user can look up unknown words in definitions and determine the meaning of these words given the context in the definition. A computer is not predisposed to determining the meaning from definitions, e.g., given the definition of *pipette* as *a slender tube for measuring or transferring*

provides a general theory of morphological performance that distinguishes most types of extragrammatical derivational processes from those determined by grammar.

Lexical Acquisition

D McCarthy, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Lexical acquisition is the production or augmentation of a lexicon for a natural language processing (NLP) system. The resultant lexicon is a resource like a computerized dictionary or thesaurus but in a format for machines rather than people. The entries in a lexicon are lexemes, and the information acquired for these includes the forms, meanings, collocations, and associated statistics.

Acquisition is vital for NLP because the performance of any system that processes text or speech is dependent on its knowledge of the vocabulary of the language being processed. As well as an extensive grasp of the vocabulary, a system needs a means to cope when it encounters a word that it has not seen before. Because of the requirements of an application, there may be a case for limiting a system to the words appropriate within a specific domain. However, even in a specific domain, everyday words will be used and there will be additional domain-specific terminology. It is possible, and sometimes appropriate, to build a system that can run using only a small vocabulary. However, it is nevertheless necessary to acquire appropriate forms and meanings of the lexemes for the given domain. The lexical information required is not explicitly listed in any available resource, and getting humans to provide it is extremely costly. For this reason lexical acquisition is frequently referred to as the bottleneck for NLP. In order to produce lexicons for deployable NLP systems, lexical acquisition must be automated.

There are significant differences between the requirements of a lexicon intended for a computer system and the contents of a dictionary or thesaurus written for humans. Machine-readable dictionaries and thesauruses (MRDs and MRTs) have been designed for online use by humans. If the information contained were sufficient then one could permit a NLP system to use them directly, or after some simple reformatting. However, while it was hoped that machine-readable resources produced by humans for humans would be a viable means of populating lexicons, it is now widely recognized that this method will not work. The resources are prone to omissions, errors, and inconsistencies. Furthermore, the lexicographers producing these resources rely on the fact that users have an adequate grasp of the language, knowledge of the world, and basic intelligence to understand the definitions supplied and fill in any gaps. For example, a human user can look up unknown words in definitions and determine the meaning of these words given the context in the definition. A computer is not predisposed to determining the meaning from definitions, e.g., given the definition of *pipette* as *a slender tube for measuring or transferring*

small quantities of liquid, a computer may need to look up the meaning of *tube*, and would then be faced with the ambiguity that *tube* can mean *metro* as well as *hollow object*.

In addition to the errors, omissions and problems of format, NLP systems require information that is simply not present in a dictionary because humans do not need it. A prime example of this deficiency is frequency information. Frequency information permits systems to concentrate effort on the more likely analyses or utterances. This evidence is important since a great many interpretations are possible for most utterances, and most information can be said in more than one way. The majority of NLP systems rely on statistical processing that requires probability estimates obtained from frequency data. Not only do lexicons require frequency data, but they need to be tailored to the domain of the application. Man-made resources are typically general purpose.

For these reasons, most acquisition is now performed automatically from corpora, comprising large collections of real life text or speech samples. The corpus is chosen with regard to the intended domain of the application. Man-made resources are still often used in hybrid systems that collect the frequency data from the corpora but with recourse to the entities provided in the MRDs. There are also cases where acquisition is performed semi-automatically, with human lexicographers guiding the acquisition process or correcting the output.

Resources

Machine-Readable Dictionaries

Dictionaries contain entries for words that are broken down into the various meanings, or senses, of the word. These meanings are supplied with definitions and part-of-speech information, i.e., whether this use of the word is a noun, verb, adjective, or adverb. Other information is also sometimes available, for example the various morphological forms of the word, its phonological realization and information on syntactic behavior. Some dictionaries also include a subject code or domain label, for example, the *Longman Dictionary of Contemporary English* (LDOCE) (Proctor, 1978), or the *Oxford Dictionary of English* (Soanes and Stevenson, 2003). LDOCE also provides information on the semantic class of the arguments of verbs (for the subject, direct object, and indirect object grammatical slots).

Machine-Readable Thesauruses

Entries in thesauruses provide words with similar meanings. The most widely used MRT is WordNet (Fellbaum, 1998) not just because of the wealth of information, particularly semantic, but also because of its free availability. WordNet is an online thesaurus, organized by semantic relations rather than alphabetically. Words are classified by their part-of-speech (noun, verb, adjective, and adverb). They are then subdivided into small classes called 'synsets' where members are near synonyms of each other. These synsets are then linked together by semantic relationships such as hyponymy (nouns and verbs), meronymy (nouns), antonymy (adjectives), and entailment (verbs). Figure 1 illustrates some of these relationships.

Similar resources are available in other languages, for example, a number of WordNets are being distributed in other languages, notably European languages. There are also dictionaries in other languages organized by semantic relationships, for example, EDR (NICT, 2002).

Corpora

Corpora range in the amount of linguistic annotation provided. Some occur in raw form, as archives of text or spoken language. Some are 'balanced' with a mix of texts selected from a range of genres and domains, for example, the British National Corpus (Leech, 1992). This corpus also includes part-of-speech annotations for every word form. Other annotations are sometimes available, for example the Penn Treebank II (Marcus, 1995) includes syntactic analyses that have been hand-corrected from the output of an automatic parser. SemCor (Landes *et al.*, 1998) is a 220 000-word corpus that has been manually annotated with WordNet sense tags.

Acquisition from labeled data (supervised acquisition) is often more accurate than acquisition from raw text (unsupervised acquisition). However, annotations are costly to create and are not always available for a particular language or text type. Unsupervised systems are useful when there is no labeled data to learn from. The lack of annotation for corpora is compensated in part by the size of the corpora available.

Multilingual Resources

As well as monolingual dictionaries and corpora, there are also some multilingual resources available. These resources are potentially extremely useful since the redundancies and different forms in one language can help resolve ambiguities in another. CELEX (Baayen *et al.*, 1995) contains databases for English, Dutch, and German that includes syntactic, morphological, phonological, and orthographic information.

Figure 1 Some semantic relationships in WordNet.

Other multilingual dictionaries and thesauruses often have links between words with the same meaning in different languages. Multilingual corpora include both parallel corpora, where the data in one language has been translated into another, and comparable corpora where essentially the same content, such as news events, has been collected from different sources.

Automatic Techniques

There are a wide variety of techniques used for lexical acquisition, and the appropriate solution will depend on the information sought and the resources available. The simplest approach is to look up information directly in an existing MRD. For many types of information this approach is not possible because the information is not present or complete. Furthermore, it is quite possible that a usage of an existing word will not be listed in a MRD.

Alternatively, a system can be built to learn the information from data, referred to as training data, usually obtained from corpora. An extremely simple method is to apply pattern-matching techniques to the training data. This method has yielded success for some types of information, notably 'is-a' semantic relations between nouns. So, for example using the pattern, 'X is a type of Y' → X is-a Y and the text, *A dog is a type of animal*, a system can be made to infer dog is-a animal.

The majority of approaches use some form of statistics. There are straightforward applications of textbook statistics, e.g., the chi-square or *t*-test, to frequency counts of word co-occurrences. A significant problem for all statistical approaches is that the frequency distributions of linguistic phenomena are skewed so that a minority of forms or meanings takes up the majority of instances in a corpus. This inequity means that systems need to cope with the problem of data sparseness, and that for a great many forms it is hard to get good frequency estimates.

There are more complicated methods that incorporate statistical estimates. There are techniques that use concepts from information-theory. For example, Lin (1998) proposed a measure of similarity that takes into account the shared contexts of words.

Machine-learning techniques, which may also involve a statistical component, induce lexical information from examples. The examples can be labeled (supervised training) or unlabeled (unsupervised). In supervised approaches, often referred to as memory-based learning, stored examples can be simply compared to a new candidate, and the closest fitting neighbor is used to obtain a label for the new candidate. Alternatively, instead of simply storing the examples, a system can generalize from the examples and find a decision tree that best partitions the examples according to the labels. Unsupervised learning is frequently performed by clustering entities according to features, e.g., words according to the contexts in which they occur.

For example, the verbs in Table 1 might be clustered into three groups according to the frequency of their direct objects.

Table 1 Clustering verbs by the frequency of their direct objects

	Verbs							
Direct objects	*eat*	*consume*	*devour*	*construct*	*build*	*begin*	*start*	*commence*
house	2	1	0	31	72	21	10	1

The Entries and Acquired Information

The entries stored in a lexicon are referred to as lexemes. They are listed with lexical information depending on the needs of the application that the system is being produced for. For example, a spelling checker may only require orthographic information to render the lexeme into word forms that can occur in text. Additional lexical information is often needed by applications including pronunciation; part-of-speech; morphology; syntax, argument structure; preferences; semantics; pragmatics; and multiwords.

Pronunciation

The phonetic realization of a word is needed by systems that recognize or produce speech rather than text. Word-specific pronunciation can be learned automatically from examples. This possibility has been demonstrated for Dutch (Daelemans and Durieux, 2000). In this memory-based approach, the examples to teach the system were constructed by aligning the letters of a word and its context to the phonemes. Pronunciations of new words are acquired by comparing the input letter sequence to stored examples. The approach could be applied to a language other than Dutch, provided that a grapheme-phoneme alignment is possible for that language. In other work, stress has also been acquired automatically using memory-based learning techniques (Daelemans *et al*., 1994).

Part-of-Speech

The part-of-speech of a given word is important for morphological, syntactic, and semantic analysis. Indeed, since a given word may belong to different parts-of-speech, frequency information is often required in order to arrive at the most likely part-of-speech for a word in a given sentence. This information is typically obtained using a labeled corpus, but the possible parts-of-speech for a word can also be induced using frequency information of other words in the context (Finch and Chater, 1994).

While acquisition of part-of-speech is required for all words, further information on morphology, syntax, and semantics is usually acquired for nouns, verbs, adjectives, and adverbs only. These are open-class words that change meaning and behavior depending on the domain and with time. The set of open class words increases, whereas closed-class words are a restricted set for which most of the information can be obtained in one go and does not change radically.

Morphology

The word forms that a lexeme can take are important for NLP systems. The variety of forms is due to inflections (to indicate number, gender, tense, etc., for example, *eat* versus *ate*) and derivations (from a different part-of-speech, for example, *central centralize*). While word forms are explicit in corpus data, acquisition is not straightforward because of both unseen and ambiguous forms. It is quite common for a given form to serve several functions (syncretism). For example, one cannot distinguish between the past tense and past participle forms of many English verbs, e.g., *I jumped* versus *I have jumped*. There are also cases where word forms of the same lexeme bear no morphological relationship e.g., *go* and *went*. Morphologically related words can be found using a combination of string edit measures, which measure the changes required to turn one string into another, and word co-occurrence statistics designed to capture semantic similarity. Neural networks, a method useful for detecting patterns in data, have been used for learning roots and suffixes from input data. Furthermore, the stems, suffixes, and families (or signatures) of suffixes of a language can

all be learned from corpora, for example, using methods from information theory that strive for the best compromise between a compact model and a good explanation of the data (Goldsmith, 2001).

Syntax, Argument Structure, and Preferences

The syntactic structures that a word can occur in are important for understanding utterances and ensuring grammatical output. There is a good deal of work on the argument structure of verbs since these play a key role relating the phrases within sentences and verbs have the most complex syntactic constructions. The correct arguments of a verb are more easily identified in a sentence when the parser knows the types of construction (subcategorization frames) possible for a verb. For example, information that *give* can take both a single object and a double object construction allows both the following interpretations:

(1) 'She gave (the dog) (bones).' i.e., the dog gets the bones
'She gave (the dog bones).' i.e., some unidentified entity gets dog bones

Subcategorization information is acquired with rudimentary syntactic analysis (without subcategorization frame information) and statistical filters that reduce the impact of noise in the analysis. Subcategorization acquisition has included basic sets of frames (Brent, 1993), as well as more detailed sets (Briscoe and Carroll, 1997) and languages other than English.

As well as argument structure, the semantic classes of arguments are acquired. For example, the direct objects of the verb *eat* are typically types of food. These are referred to as selectional restrictions, implying hard and fast constraints, or preferences. Preferences are usually acquired as a set of semantic classes, each with a score representing the strength of the preference for that class, as illustrated in Table 2.

Many systems have followed the approach of Resnik (1998) and used corpus counts collected over WordNet. However semantic classes induced from corpus data (see below) can also be used for representation.

Given both subcategorization frames and selectional preferences, alternative ways of expressing the verbs underlying arguments can be identified. For example, the alternation:

(2) 'The boy broke the window.' ↔ 'The window broke.'

can be observed by detecting the subcategorization frames for the verb *break* and observing the similarity between the preferences for words that occupy the object slot in the first variant with those in the subject slot in the alternate form. These are known as diathesis alternations and are important because they are a link between the syntax and semantics of the verb. Verbs sharing diathesis patterns typically also share semantic characteristics (Levin, 1993).

Table 2 Selectional preferences for the direct object slot of the verb *start*

Semantic class	*Preference score*	*Example direct objects*
time period	0.1	week, day
communication	0.08	speech, yelling
activity	0.2	construction, war, migration
entity	0.14	car, meal

As well as detecting diathesis patterns directly, researchers have demonstrated that syntactic and semantic features can be used to cluster verbs into classes relevant to these alternations. Merlo and Stevenson (2001) have a method where manually selected and linguistically motivated features are used for classifying verbs into three classes relating to a selection of alternations using a supervised decision tree machine learning algorithm. Subsequent work has shown that a multilingual approach can facilitate acquisition using features available in another language to help make distinctions in the target language.

Semantics

The meanings of words are required for some applications. For example, given the query, *Who employs Mr. Smith* and the sentence, *Mr. Smith works for Hydro-Systems*, lexical knowledge of the relationship between *employ* and *work* can be used to ensure an appropriate answer. Words can have more than one meaning, and this multiplicity may also need taking into account. For example, a question such as *Who is on the board?* would not want responses concerning planks of wood. One problem with including word meanings in lexicons is that the set of possible meanings is vast. When defining the meanings of a word it is possible to arrive at an extremely fine-grained classification with many different senses that are related, though subtly different in some way. For example, the verb *break* has 59 senses in WordNet version 2.0.

Having a fine-grained sense inventory is not always beneficial for NLP, since distinguishing these meanings in text is not easy even for human annotators. There is typically a large skew in the frequency distribution of senses so that one or two senses of a word are much more predominant than the others. This emphasis is particularly the case when dealing with

language in a given domain. As a consequence, much acquisition of other information, such as subcategorization, has assumed a predominant sense for a word and not differentiated information by sense.

Rather than use a man-made resource for lexical meaning, many have exploited the fact that semantically similar words tend to occur in similar contexts. These are distributional approaches that attempt to find similar words given input data such as that in Table 1. The data can be clustered to give distinct classes, e.g., (*begin*, *commence*), (*eat*, *consume*, *devour*), and (*construct*, *build*). Or, instead of explicitly creating classes, a target word can simply be listed with a specified number of 'nearest neighbor' words as an acquired thesaurus, e.g., *eat*: *consume devour*, etc.

These lists of nearest neighbors are produced to avoid losing information during the clustering process. The neighbors are associated with the distributional similarity scores used for ordering them. Nearest neighbors or induced classes can be used by an NLP system to provide evidence when there is not enough data for a related word and to cope with the fact that things can be said in different ways, depending on subtle nuances.

As well as finding related words, different senses of the same word can be found from the data by either (i) clustering the nearest neighbors of a word (Pantel and Lin, 2002) according to the contexts that these neighbors occur in or (ii) clustering the contexts of individual tokens of the word (Schütze, 1998).

Another approach to determining the meanings of words from data is to use parallel corpora and define senses where a word in one language is realized by more than one word in another language (Resnik and Yarowsky, 2000). This technique can be done with more than two languages, and with languages that are more distantly related since the ambiguities are more likely to differ. The sense inventory produced by this strategy will be relevant for translation between those languages. This approach contrasts with using a predefined sense inventory such as WordNet, where the senses may be too fine-grained and never reflect ambiguities that actually give rise to problems for an application such as machine translation.

As an alternative to identifying senses in text, there are also approaches that discover patterns of use within a generative lexicon framework (Pustejovsky, 1995) rather than assuming distinct senses. Pustejovsky and Hanks (2004) propose a semi-automatic method using selectional preference patterns identified by hand.

Current work on acquisition of lexical semantics focuses on relationships between linguistic units. Model-theoretic semantics where linguistic units are related to entities in the world have not received much attention. Though recently there has been work on acquisition of lexical semantics from non-linguistic data (Barzilay *et al.*, 2003).

Pragmatics

One way of conveying the user's intent in an utterance is the choice of words. This choice can reflect stylistic preferences such as formality and attitude, for example, knowing whether to use *demand*, *stipulate*, *request*, or *ask* in a given utterance. Such information is particularly important for generation, but could also be useful for a system trying to detect sentiment. It is not obvious how to identify the nuances of meaning of near-synonyms from raw data. Work has been done however extracting this sort of information from MRDs (Inkpen and Hirst, 2001). Work on sentiment detection identifies words that are subjective, and those that indicate a positive or negative sentiment by partitioning good and bad reviews. Though sentiment detection is not focused on contrasting the meanings of semantically related words, e.g., *brave* versus *foolhardy*, it might benefit from such information.

Multiwords

Lexemes can have more than one word stem, for example, *post office*. These are referred to as 'multiwords' and are phrases where the meaning is not compositional, that is, the meaning of the phrase is not simply a sum of the meaning of component words. Multiwords are important for interpretation and for production of natural sounding text. There are a variety of multiword types including idioms, specific constructions such as phrasal verbs and collocations, i.e., words which occur together by convention (Sag *et al.*, 2002).

Acquisition of multiwords is typically done using a combination of a statistical association measure and a linguistic filter (Smadja, 1993). Another approach is to search for potential candidates with syntactic analysis and statistics, and then look for signs of non-compositionality. This approach can be done by finding a lack of combinations of component words with substitutions from the same semantic class in a corpus. For example, we find *red herring* in corpus data but not usually *yellow herring*. Both WordNet and acquired thesauruses can be used to define the semantic classes. Non-compositionality has also been detected using distributional approaches to demonstrate that the semantics of the multiword has very different characteristics to that anticipated, given the component words.

Updating the Lexicon

Most lexical acquisition systems have been designed to extract lexical knowledge from resources in advance and subsequently deploy the lexicon within a NLP system. However, due to data sparseness, the creative way in which language is used, and the very nature of open-class words, there will inevitably be linguistic forms and meanings that have not been acquired beforehand. A method is required for handling new phenomena as they occur.

One updating task is the detection of words that are not already in the lexicon. This process must filter misspellings and non-real words, for example codes, from lists of candidates. Genuine words can be identified by examining the letter combinations and ensuring that these would produce regular sounding words for the given language. This process is performed using frequency data collected over character sequences from a given corpus (Park, 2002).

When obtaining estimates for unseen word forms, for example, morphological forms, it might seem appropriate to take an average over forms observed in a training corpus. However, Baayen and Sproat (1996) demonstrate that care should be taken since frequent forms behave differently to infrequent forms. They recommend using estimates from forms that have occurred only once, rather than an average over all forms in the training corpus.

As well as finding new words, there are also methods aimed at learning lexical information on the fly. Part-of-speech information is obtained using morphological information. Morphological information can also be used to identify the basic semantic category of a word, alongside other information, such as collocations. A chief motivation for thesaurus acquisition and clustering is that these will help with prediction of unseen behavior for members within a given class. There are also systems that place new word forms into a predefined inventory, such as WordNet.

Evaluation

The output of lexical acquisition systems must be evaluated. There are two main ways in which this evaluation can be done. Firstly, the performance of the lexicon on a task can be measured. A task-based evaluation is appropriate when there is a specific task that the lexicon is being designed for, however a ready-made 'plug and play' application is not always available. Acquired lexical information have often been evaluated on sub-tasks, so for example, selectional preferences have been evaluated on their performance at determining whether a given prepositional phrase should be attached to the preceding verb or noun phrase. For example, given the sentence *The boy hit the man with a stick*, the preference of *hit with a stick* is contrasted with the preference for *man with a stick*.

The second method is evaluation of the quality and coverage of the lexical entries. Evaluating the entries is often done by consulting a man-made resource referred to as a 'gold standard.' The obvious problem with using such a resource, or even a combination of several resources, is that there will be rare forms in the gold standard that are simply not attested in the corpus data used for training. Likewise the very need for lexical acquisition means that there will be legitimate information that is omitted from a gold standard. For this reason, evaluation is also performed by examining a manually annotated sample of text input to the acquisition process to verify that what is acquired does indeed reflect what is attested in the corpus, and also the adequacy of any acquired frequency estimates. Human experts can also perform a manual verification of the acquired information. This approach is used to identify the errors in the output rather than to prove that all information available in the input was successfully extracted. There are further problems when there is no widely agreed upon classification, as is the case when acquiring semantic classes, or no precise definition of the phenomena being acquired, for example, in the case of multiword acquisition. These problems show up in a lack of agreement between human judges. For example, if asked to determine the multiwords in:

(3) 'They ate the chocolate cake in the wendy house.'

human judges might unanimously decide that *wendy house* is a multiword, but will potentially have more trouble with *chocolate cake* since the interpretation is more standard.

Future Directions

Currently, acquisition focuses on coverage and accuracy of extracted information. There are issues of organization and representation that received attention when lexicons were manually constructed. Expressive representations with inheritance of features capture generalizations and avoid unnecessary repetition while handling exceptions. Acquisition from corpora currently focuses on acquiring one type of information as a flat list, perhaps ordered by frequency, alphabetically or arbitrarily. While issues of representation have been seen as important in the semi-automatic construction of some lexicons from machine readable resources (Copestake, 1992), there

has been little done on acquiring structured information from corpora. One reason that lexical acquisition from corpora has not used more complex representations is due to the widespread use of statistics and absence of a formal model for storing probability estimates in an inheritance framework. If such a framework were developed, acquisition of information into more complex representations might help in identifying cross-lingual generalizations and establishing correlations between different types of linguistic information, for example, linking a semantic class with syntactic behavior.

With the increasing variety of information required, lexical acquisition continues to play a crucial role within NLP. The importance is emphasized by many large-scale projects focusing on specific aspects of lexical acquisition, e.g., the Multiword Expression Project and MEANING. The process of acquisition has been greatly enhanced by vast quantities of data available in corpora, along with statistical techniques to derive the information from the data and the increasing computational power available. In recent years, new resources have proved useful, e.g., comparable corpora in different languages and the World Wide Web. In the future, further resources could be exploited. Speech or image processing might provide the prosody and visual cues that humans use when acquiring vocabulary. Dialogue systems might provide feedback when acquisition has gone wrong.

Lexical Conceptual Structure

J S Jun, Hangkuk University of Foreign Studies, Seoul, Korea

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The lexical conceptual structure (LCS) or simply the conceptual structure (CS) is an autonomous level of grammar in conceptual semantics (Jackendoff, 1983, 1990, 1997, 2002), in which the semantic interpretation of a linguistic expression is explicitly represented. Jackendoff's (1983) original conception is to posit a level of mental representation in which *thought* is couched (cf. the *language of thought* in Fodor, 1975). CS is a relay station between language and peripheral systems such as vision, hearing, smell, taste, kinesthesia, etc. Without this level, we would have difficulty in describing what we see and hear.

There are two ways to view CS in formalizing a linguistic theory. One is to view CS as a nonlinguistic system that serves as an interface between meaning and nonlinguistic modalities. Then, we need another level of representation for meaning (cf. Chomsky's [1981, 1995] LF); and CS is related to the linguistic meaning by pragmatics as shown in **Figure 1**. This is the view of Katz and Fodor (1963), Jackendoff (1972), Katz (1980), and Bierwisch and Schreuder (1992). The alternative conception is to view CS as the semantic structure. The linguistic meaning as well as nonlinguistic information compatible with sensory and motor inputs is directly represented in CS. CS is related with other linguistic levels such as syntax and phonology by correspondence rules, and therefore CS is part of the lexical information (*hence called* LCS) as shown in **Figure 2**. This is the current view of conceptual semantics.

One argument that supports the latter view comes from generic judgment sentences. In the standard view of linguistic meaning, judgments of superordination, subordination, synonymy, entailment, etc., are *linguistic*. We judge that 'bird' and 'chicken' make a superordinate-subordinate pair; that in some dialects 'cellar' and 'basement' are synonymous; and that 'Max is a chicken' entails 'Max is a bird.' Linguistic judgments of this sort are formalized in theories such as meaning postulates (Fodor, 1975) and semantic networks (Collins and Quillian, 1969).

Jackendoff (1983) points out one problem in formalizing these judgments from a purely linguistic perspective: judgments of superordination and subordination, for instance, are directly related to judgments of generic categorization sentences such as 'A chicken is a bird.' The judgment about generic categorization is, however, not entirely linguistic or semantic, in that it behaves creatively enough to include ambiguous cases such as (1) below.

(1a) A piano is a percussion instrument.
(1b) An australopithecine was a human.
(1c) Washoe (the chimp)'s sign system is a language.
(1d) An abortion is a murder.
(Jackendoff, 1983: 102)

We make generic categorization judgments about (1) not on the basis of meaning postulates or semantic networks but on the basis of our factual, often

Lexical Conceptual Structure

J S Jun, Hangkuk University of Foreign Studies, Seoul, Korea

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The lexical conceptual structure (LCS) or simply the conceptual structure (CS) is an autonomous level of grammar in conceptual semantics (Jackendoff, 1983, 1990, 1997, 2002), in which the semantic interpretation of a linguistic expression is explicitly represented. Jackendoff's (1983) original conception is to posit a level of mental representation in which *thought* is couched (cf. the *language of thought* in Fodor, 1975). CS is a relay station between language and peripheral systems such as vision, hearing, smell, taste, kinesthesia, etc. Without this level, we would have difficulty in describing what we see and hear.

There are two ways to view CS in formalizing a linguistic theory. One is to view CS as a nonlinguistic system that serves as an interface between meaning and nonlinguistic modalities. Then, we need another level of representation for meaning (cf. Chomsky's [1981, 1995] LF); and CS is related to the linguistic meaning by pragmatics as shown in Figure 1. This is the view of Katz and Fodor (1963), Jackendoff (1972), Katz (1980), and Bierwisch and Schreuder (1992). The alternative conception is to view CS as the semantic structure. The linguistic meaning as well as nonlinguistic information compatible with sensory and motor inputs is directly represented in CS. CS is related with other linguistic levels such as syntax and phonology by correspondence rules, and therefore CS is part of the lexical information (*hence called* LCS) as shown in Figure 2. This is the current view of conceptual semantics.

One argument that supports the latter view comes from generic judgment sentences. In the standard view of linguistic meaning, judgments of superordination, subordination, synonymy, entailment, etc., are *linguistic*. We judge that 'bird' and 'chicken' make a superordinate-subordinate pair; that in some dialects 'cellar' and 'basement' are synonymous; and that 'Max is a chicken' entails 'Max is a bird.' Linguistic judgments of this sort are formalized in theories such as meaning postulates (Fodor, 1975) and semantic networks (Collins and Quillian, 1969).

Jackendoff (1983) points out one problem in formalizing these judgments from a purely linguistic perspective: judgments of superordination and subordination, for instance, are directly related to judgments of generic categorization sentences such as 'A chicken is a bird.' The judgment about generic categorization is, however, not entirely linguistic or semantic, in that it behaves creatively enough to include ambiguous cases such as (1) below.

(1a) A piano is a percussion instrument.
(1b) An australopithecine was a human.
(1c) Washoe (the chimp)'s sign system is a language.
(1d) An abortion is a murder.
(Jackendoff, 1983: 102)

We make generic categorization judgments about (1) not on the basis of meaning postulates or semantic networks but on the basis of our factual, often

Figure 1 CS as a nonlinguistic system (adapted from Jackendoff R (1983). *Semantics and cognition*. Cambridge, MA: MIT Press, 20, with permission).

Figure 2 CS as part of the linguistic system (adapted from Jackendoff R (1983). *Semantics and cognition*. Cambridge, MA: MIT Press, 21, with permission).

political, world knowledge. For instance, our judgment about (1d) is influenced by our political position, religion, and knowledge about biology. This is analogous to Labov's (1973) dubious 'cup-bowl' judgment, which obviously resorts to nonlinguistic encyclopedic knowledge as well as the linguistic type system. CS is, by definition, the level that represents encyclopedic knowledge as part of our thought. Hence, we should refer to CS to make generic categorization judgments about (1).

Jackendoff's (1983) puzzle is summarized, as follows. We make judgments of semantic properties such as superordination and subordination at the level of semantic structure. We make generic categorization judgments at the level of CS as shown by (1). If the semantic structure were separated from CS, we would fail to catch the obvious generalization between the superordinate-subordinate judgment and the generic categorization judgment. If, by contrast, CS were the semantic structure, we would have no trouble in accounting for the intuitive identity between the two judgments. Therefore, CS is the semantic structure. For more arguments to support the view that CS is the semantic structure, see Jackendoff (1983: Ch. 6).

Overview of Conceptual Semantics

Autonomy of Semantics

A central assumption in conceptual semantics is the autonomy of semantics. In Chomsky's view of language, syntax makes an autonomous level of grammar, whereas phonology and semantics merely serve as interpretive components (PF and LF). Jackendoff (1997) criticizes this view as *syntactocentric*, and

provides convincing arguments to support his thesis that phonology and semantics as well as syntax make autonomous levels of grammar.

We find numerous pieces of evidence for the autonomy of semantics in the literature of both psycholinguistics and theoretical linguistics. Zurif and Blumstein's (1978) pioneering work shows that Wernicke's area is the center of semantic knowledge in the brain in comparison with Zurif, Caramazza and Myerson's (1972) previous finding that Broca's area is the center of syntactic knowledge. Swinney's (1979) classical work on lexical semantic priming shows that lexical semantics is independent of the grammatical contexts like the movement chain in a sentence. Piñango, Zurif, and Jackendoff (1999) report more workload for the online processing of aspectual coercion sentences (e.g., *John jumped for two hours*) than for the processing of syntactically equivalent noncoerced sentences (e.g., *John jumped from the stage*).

Semantic categories are not in one-to-one correspondence with syntactic categories. For instance, all physical object concepts correspond to nouns, but not all nouns express physical object concepts; e.g., *earthquake* and *concert* express event concepts. All verbs express event/state concepts, but not all event/state concepts are expressed by verbs; e.g., *earthquake* and *concert* are nouns.

Contrary to Chomsky's (1981) theta criterion, we have plenty of data that shows mismatch between syntactic functions and thematic roles. For instance, the semantic interpretation of *buy* necessarily encodes both the transfer of money from the buyer to the seller and the transfer of the purchased entity from the seller to the buyer. Among the three semantic arguments, i.e., the buyer, the seller, and the purchased object, only the buyer and the purchased entity are syntactic arguments (e.g., *John bought the book*). The seller is syntactically expressed as an adjunct (e.g., *John bought the book from Jill*). Moreover, the buyer plays the source role of money and the target role of the purchased entity simultaneously; the seller plays the source role of the purchased entity and the target role of money simultaneously. In short, the buyer and the seller have multiple theta roles even though each of them corresponds to one and only one syntactic entity.

A simple semantic distinction often corresponds to many syntactic devices. For instance, telicity is expressed by such various syntactic devices as choice of verb (2a), choice of preposition (2b), choice of adverbial (2c), choice of determiner in the subject NP (2d) and in the object NP (2e), and choice of prepositional object (2f) (Jackendoff, 1997: 35).

(2a)	John *destroyed* the cart (in/*for an hour).	→ Telic
	John *pushed* the cart (for/*in an hour).	→ Atelic
(2b)	John ran *to* the station (in/*for an hour).	→ Telic
	John ran *toward* the station (for/*in an hour).	→ Atelic
(2c)	The light flashed *once* (in/*for an hour).	→ Telic
	The light flashed *constantly* (for/*in an hour).	→ Atelic
(2d)	*Four people* died (in/*for two days).	→ Telic
	People died (for/*in two days)	→ Atelic
(2e)	John ate *lots of peanuts* (in/*for an hour)	→ Telic
	John ate *peanuts* (for/*in an hour).	→ Atelic
(2f)	John crashed into *three walls* (in/*for an hour)	→ Telic
	John crashed into *walls* (for/*in an hour)	→ Atelic

To sum up, the mapping between syntax and semantics is not one-to-one; rather, it is one-to-many, many-to-one, or at best many-to-many. The mapping problem is not easy to explain in the syntactocentric architecture of language. The overall difficulty in treating semantics merely as an interpretive component of grammar along with a similar difficulty treating phonology as an interpretive component (cf. Jackendoff, 1997: Ch. 2) leads Jackendoff to propose a tripartite architecture of language, in which phonology, syntax, and semantics are all independent levels of grammar licensed by phonological formations rules, syntactic formation rules, and conceptual/semantic formation rules respectively, and interfaced by correspondence rules between each pair of modules, as shown in Figure 3.

Lexical Conceptual Structure

Conceptual semantics assumes striking similarities for the organization of CS with the structural organization of syntax. As syntax makes use of syntactic categories, namely syntactic parts of speech like nouns, adjectives, prepositions, verbs, etc., semantics makes use of semantic categories or semantic parts of speech such as Thing, Property, Place, Path, Event, State, etc. As syntactic categories are motivated by each category member's behavioral properties in syntax, semantic or ontological categories are motivated by each category member's behavioral properties in meaning.

Syntactic categories are combined by syntactic phrase-structure structure rules into larger syntactic expressions; likewise, semantic categories are combined by semantic phrase-structure rules into larger semantic expressions. The syntactic representation is structurally organized, so we can define dominance or government relations among syntactic constituents; likewise, the semantic representation is structurally organized, so we can define grammatically significant hierarchical relations among semantic constituents. Various syntactic phrase-structure rules can be generalized into a rule schema called X-bar syntax (Jackendoff, 1977); likewise, various semantic

Figure 3 The tripartite parallel architecture (reproduced from Jackendoff R (2002). *Foundations of language: brain, meaning, grammar, evolution.* Oxford: Oxford University Press).

phrase-structure rules can be generalized into a rule schema called X-bar semantics (Jackendoff, 1987b).

Ontological Categories Ontological categories are first motivated by our cognitive layouts. To mention some from the vast psychology literature, Piaget's developmental theory of *object permanence* shows that infants must recognize objects as a whole, and develop a sense of permanent existence of the objects in question when they are not visible to the infants. Researchers in language acquisition have identified many innate constraints on language learning like reference principle, object bias, whole object principle, shape bias, and so on (cf. Berko Gleason, 1997). For instance, children rely on the assumption that words refer to objects, actions, and attributes in the environments by reference principle. Wertheimer's (1912) classical experiment on *apparent movement* reveals that humans are equipped with an innate tendency to perceive the change of location as movement from one position to the other; the apparent movement experiment renders support for the expansion of the event category into function argument structures like $[_{Event}$ GO $([_{Thing}], [_{Path}])]$.

Ontological categories also have numerous linguistic motivations. Pragmatic anaphora (exophora) provides one such motivation. In order to understand the sentence in (3), the hearer might have to pick out the referent of *that* among several entities in the visual field. If the hearer did not have object concepts to organize the visible entities, (s)he could not pick out the proper referent of the pragmatic anaphora *that*. The object concept involved in the semantic interpretation of (3) motivates the ontological category Thing.

(3) I bought *that* last night.

The category Thing proves useful in interpreting many other grammatical structures. It provides the basis of interpreting the Wh-variable in (4a); it supports the notion of identity in *the same* construction in (4b); and it supports the notion of quantification as shown in (4c).

(4a) *What* did you buy last night?
(4b) John bought *the same thing* as Jill.
(4c) John bought *something/everything that Jack bought*.

Likewise, we find different sorts of pragmatic anaphora that motivate ontological categories like Place (5a), Direction (5b), Action (5c), Event (5d), Manner (5e), and Amount (5f).

(5a) Your book was *here/there*.
(5b) They went *there* yesterday.
(5c) Can he do *this/that*?
(5d) *It* happened this morning.
(5e) Bill shuffled a deck of cards *this* way.
(5f) The man I met yesterday was *this* tall.

These ontological categories provide innate bases for interpreting Wh-variables, the identity construction, and the quantification, as shown in (6)–(8).

(6a) *Where* was my book?
(6b) *Where* did they go yesterday?
(6c) *What* can he do?

(6d) *What* happened this morning?
(6e) *How* did Bill shuffle a deck of cards?
(6f) *How* tall was the man you met yesterday?

(7a) John put the book on *the same place* as Bill.
(7b) John went *the same way* as Bill.
(7c) John did *the same thing* as Bill.
(7d) *The same thing* happened yesterday as happened this morning.
(7e) John shuffled a deck of cards *the same way* as Bill.
(7f) John is *as tall as* the man I met yesterday.

(8a) John put the book at *some place that Bill put it*.
(8b) John went *somewhere that Bill went*.
(8c) John did *something Bill did*.
(8d) *Something that happened this morning* will happen again.
(8e) John will shuffle cards in *some way that Bill did*.
(8f) (no parallel for amounts)

For more about justifying ontological categories, see Jackendoff (1983: Ch. 3).

Conceptual Formation Rules Basic ontological categories are expanded into more complex expressions using function-argument structural descriptions. (9) shows such expansions of some ontological categories.

(9a) EVENT → [$_{\text{Event}}$ GO (THING, PATH)]
(9b) EVENT → [$_{\text{Event}}$ STAY (THING, PLACE)]
(9c) EVENT → [$_{\text{Event}}$ CAUSE (THING or EVENT, EVENT)]
(9d) EVENT → [$_{\text{Event}}$ INCH (STATE)]
(9e) STATE → [$_{\text{State}}$ BE (THING, PLACE)]
(9f) PLACE → [$_{\text{Place}}$ PLACE-FUNCTION (THING)]
(9g) PATH → [$_{\text{Path}}$ PATH-FUNCTION (THING)]

The function-argument expansion is exactly parallel with rewriting rules in syntax (e.g., S → NP VP; NP → Det (AP)* N; VP → V NP PP), and hence can be regarded as semantic phrase-structure rules. The semantic phrase-structure rules in (9) allow recursion such as syntactic phrase-structure rules: an Event category can be embedded in another Event category as shown in (9c). We also can define hierarchical relations among conceptual categories in terms of the depth of embedding as we define syntactic dominance or government in terms of the depth of embedding in syntactic structures. The depth of embedding in CS plays a significant role in explaining such various grammatical phenomena as subject selection, case, binding, control, etc. See Culicover and Jackendoff (2005) for more about these issues.

Place functions in (9f) may include IN, ON, TOP-OF, BOTTOM-OF, etc. Path functions in (9g) may include TO, FROM, TOWARD, VIA, etc. Conceptual semantics is a parsimonious theory, in that it makes use of only a handful of functions as conceptual primitives. All functions should be motivated on strict empirical grounds. This is exactly parallel with using only a handful of syntactic categories motivated on strict empirical grounds. Syntactic phrase-structure rules do not refer to unlimited number of syntactic categories. Syntactic categories such as noun, adjective, preposition, verb, etc. are syntactic primitives, and they are motivated by each category member's behavioral properties in syntax. Likewise, semantic phrase-structure rules refer to a restricted set of semantic or conceptual primitives that are empirically motivated by general properties of meaning.

Functions such as GO, BE, and STAY are empirically motivated in various semantic fields. They are the bases for interpreting spatial sentences in (10).

(10a) GO: The train traveled from Boston to Chicago.
(10b) BE: The statue stands on Cambridge common.
(10c) STAY: John remained in China.

These functions also support the interpretation of possession sentences in (11).

(11a) GO: John gave the book to Bill.
(11b) BE: John had no money.
(11c) STAY: The library kept several volumes of the Korean medieval literature.

Interpreting ascription sentences also require GO, BE, and STAY, as shown in (12).

(12a) GO: The light turned from yellow to red.
(12b) BE: The stew seemed distasteful.
(12c) STAY: The aluminum stayed hard.

One interesting consequence of having GO, BE, and STAY in both spatial and nonspatial semantic fields is that we can explain how we use the same verb for different semantic fields.

(13a) The professor turned into a driveway.	(Spatial)
(13b) The professor turned into a pumpkin.	(Ascription)
(14a) The bus goes to Paris.	(Spatial)
(14b) The inheritance went to Bill.	(Possession)
(15a) John is in China.	(Spatial)
(15b) John is a doctor.	(Ascription)
(16a) John kept the CD in his pocket.	(Spatial)
(16b) John kept the CD.	(Possession)
(17a) The professor remained in the driveway.	(Spatial)
(17b) The professor remained a pumpkin.	(Ascription)

In (13), the verb *turn* is used in both spatial and ascription sentences with the GO meaning. How do we use the same verb for two different semantic fields? Do we have to assume two different lexical entries for *turn*? Conceptual semantics does not pay anything to explain this puzzle. We do not need two different lexical entries for *turn* to explain the spatial and ascription meanings. We just posit the event function GO for the lexical semantic description or LCS for *turn* in (13). Both spatial and ascription meanings follow form the LCS for *turn*, since the function GO is in principle motivated by both spatial and ascription sentences. We can provide similar accounts for all the data in (14)–(17). For more about the general overview of conceptual semantics, see Jackendoff (1983, 1987a, 1990, 2002).

X-bar Semantics

Generative linguists in the 1950s and 1960s succeeded in showing the systematic nature of language with a handful of syntactic phrase-structure rules. But they were not sure how the phrase-structure rules got into language learners' minds within a relatively short period of time; it was a learnability problem. X-bar syntax (Chomsky, 1970; Jackendoff, 1977) opened a doorway to the puzzle. Children do not have to be born with dozens of syntactic categories; children are born with one syntactic category, namely, category X. Children do not have to learn dozens of totally unrelated syntactic phrase-structure rules separately; all seemingly different syntactic phrase-structure rules share a fundamental pattern, namely, X-bar syntax.

Jackendoff (1987b, 1990), who was a central figure in developing X-bar syntax in the 1970s, has completed his X-bar theory by proposing X-bar semantics. We have so far observed that CS is exactly parallel with the syntactic structure. Conceptual categories are structurally organized into CS by virtue of semantic phrase-structure rules, as syntactic categories are structurally organized into syntactic structure by virtue of syntactic phrase structure rules. (18) is the basic formation of X-bar syntax.

(18a) XP → Spec X'
(18b) X' → X Comp
(18c) X → [± N, ± V]

Now that CS has all parallel properties with the syntactic structure, all semantic phrase-structure rules are generalized into X-bar semantics along the same line with X-bar syntax as shown in (19).

$$(19)\quad [\text{Entity}] \rightarrow \begin{bmatrix} \text{Event Thing Place} \ldots \\ \text{Token Type} \\ \text{F}(< \text{Entity}_1, < \text{Entity}_2, < \text{Entity}_3 >>> \end{bmatrix}$$

(19) provides not only the function-argument structural generalization for all the semantic phrase-structure rules but also shows how major syntactic constituents correspond to major conceptual categories. That is, the linking between syntax and semantics can be formalized as (20) and (21).

(20) XP corresponds to [Entity]

$$(21)\quad \begin{bmatrix} \text{X}_0 \\ ___ < \text{YP} < \text{ZP} >> \end{bmatrix} \underset{\text{to}}{\text{corresponds}} \begin{bmatrix} \text{Entity} \\ \text{F}(\text{E}_1, < \text{E}_2, < \text{E}_3 >>) \end{bmatrix}$$

where YP corresponds to E_2, ZP corresponds to E_3, and the subject (if there is one) corresponds to E_1.

To sum up, the obvious similarity between (18) and (19) enables us to account for the tedious linking problem without any extra cost.

General Constraints on Semantic Theories

Jackendoff (1983) suggests six general requirements that any semantic theory should fulfill: expressiveness, compositionality, universality, semantic properties, the grammatical constraint, and the cognitive constraint.

First, a semantic theory must be observationally adequate; it must be expressive enough to describe most, if not all, semantic distinctions in a natural language. Conceptual semantics has expressive power, in that most semantic distinctions in a natural language can be represented by CS with a handful of conceptual categories plus conceptual formation rules. What is better is that the expressive power has improved since the original conception of the theory. For instance, Jackendoff (1990: Ch. 7) introduced the action tier into the theory to represent the actor/patient relation aside from motion and location. In (22a), *John* is the source of the *ball* and the actor of the throwing event simultaneously; the *ball* is a moving object, the theme, and an affected entity, the patient, simultaneously. It is quite common for one syntactic entity to bear double theta roles contra Chomsky's (1981) theta criterion; conceptual semantics captures this by representing the motion/location event in the thematic tier (22b), and the actor/patient relation in the action tier (22c).

(22a) John threw the ball.
Source Goal
Actor Patient
(22b) [$_{\text{Event}}$ CAUSE ([JOHN], [$_{\text{Event}}$ GO([BALL], [$_{\text{Path}}$ TO([. . .])])])]
(22c) [AFF([JOHN], [BALL])]

The action tier not only explains the fine semantic distinction in language but also plays a central role in such grammatical phenomena as linking and case. Besides the action tier, Jackendoff (1991) introduced

an elaborate feature system into CS to account for the semantics of parts and boundaries; Csuri (1996) introduced the referential tier into CS that describes the definiteness of expressions; Jackendoff (2002) introduced the lambda extraction and the topic/focus tier into CS. All these and many other innovations make the theory expressive enough to account for significant portion of natural language semantics.

The second constraint on a semantic theory is compositionality: an adequate semantic theory must show how the meanings of parts are composed into the meaning of a larger expression. Conceptual semantics is compositional, in that it shows how combinatorial rules of grammar compose the meanings of ontological categories into the CS of a larger expression.

The third requirement is universality: an adequate semantic theory must provide cross-linguistically relevant semantic descriptions. Conceptual semantics is not a theory of meaning for any particular language. It is a universal theory of meaning; numerous cross-linguistic studies have been conducted with the conceptual semantic formalism. See Jun (2003), for instance, for a review of many conceptual semantic studies on the argument linking and case in languages such as Korean, Japanese, Hindi, Urdu, English, Old English, French, etc.

The fourth requirement is semantic properties: an adequate semantic theory should be able to explain many semantic properties of language like synonymy, anomaly, presupposition, and so on. That is, any semantic theory must explicate the valid inference of expressions. CS provides a direct solution to this problem in many ways. The type/token distinction is directly expressed in CS, and explains most semantic distinctions made by the semantic type system. By decomposing verbs such as *kill* into *[CAUSE ([THING], [NOT-ALIVE ([THING])])]*, conceptual semantics explains how *John killed Bill* entails *Bill is dead*. For more about semantic properties, see Jackendoff (1983, 1990, 2002).

The fifth requirement is the grammatical constraint: if other things were equal, a semantic theory that explains otherwise arbitrary generalizations about the lexicon and the syntax would be highly preferable. Conceptual semantics is a theory of meaning that shows how a handful of conceptual primitives organize the vast domain of lexical semantics. Conceptual semantics also explains how semantic entities are mapped onto syntactic entities in a principled manner. For instance, the linking principle in conceptual semantics states that the least embedded argument in the CS is mapped onto the least embedded syntactic argument, namely the subject. In (22b & c), [JOHN] is the least embedded argument in both the action and thematic tiers; this explains why [JOHN] instead of [BALL] is mapped onto the subject of (22a). Jun (2003) is a conceptual semantic work on case; Culicover and Jackendoff (2005) offer conceptual semantic treatments of binding, control, and many other syntax-related phenomena. In short, conceptual semantics is an interface theory between syntax and semantics. The theory has a desirable consequence for the learnability problem, too. Language learners cannot acquire language solely by syntax or solely by semantics. As Levin (1993) demonstrates, a number of syntactic regularities are predicted by semantic properties of predicates. Conceptual semantics makes a number of predictions about syntax in terms of CS. Chomsky's explanatory adequacy is a requirement for the learnability problem; conceptual semantics is thus a theory that aims to achieve the highest goal of a linguistic theory.

The final requirement on a semantic theory is the cognitive constraint: a semantic theory should address interface problems between language and other peripheral systems like vision, hearing, smell, taste, kinesthesia, etc. Conceptual semantics fulfills this requirement, as CS is by definition a level of mental representation at which both linguistic and nonlinguistic modalities converge. Jackendoff (1987c) focuses on the interface problem, and shows, for instance, how the visual representation is formally compatible with the linguistic representation based on Marr's (1982) theory of visual perception.

Comparison with Other Works

Bierwisch and Schreuder's (B&S; 1992) work is another influential theory that makes explicit use of the term *conceptual structure*. Conceptual semantics shares two important assumptions with B&S, but there are crucial distinctions between the two theories. First, B&S also assume a separate level of conceptual structure. Their conception of CS is similar to Jackendoff's conception of CS in that CS is a representational system of message structure where non-linguistic factual/encyclopedic information is expressed. B&S, however, assume that CS strictly belongs to a nonlinguistic modality, and that the linguistic meaning is represented in another level called *semantic form* (SF). As a result, SF, but not CS, is the object of lexical semantics, and hence LCS does not make much sense in this theory. In the first section of this article, we discussed two possible views of CS; B&S take the former view of CS, whereas Jackendoff advocates the latter view.

Second, SF in B&S's theory is compositional as CS in conceptual semantics. B&S's lexical decomposition relies on two sorts of elements: constants such as DO,

MOVE, FIN, LOC, etc., and variables such as x, y, z. Constants and variables are composed into a larger expression in terms of formal logic. (23a) illustrates B&S's SF for *enter*; (23b) is the CS for the same word in Jackendoff's theory.

(23a) [y DO [MOVE y] : FIN [y LOC IN x]]
(23b) [$_{\text{Event}}$ GO ([$_{\text{Thing}}$], [$_{\text{Path}}$ TO ([$_{\text{Place}}$ IN ([$_{\text{Thing}}$])])])]

One reason B&S maintain a purely nonlinguistic CS as well as a separate SF is that factual or encyclopedic knowledge does not seem to make much grammatical contribution to language. To B&S, there is a clear boundary where the *semantic* and the *encyclopedic* diverge.

Pustejovsky's (1995) generative lexicon (GL) theory is interesting in this regard. GL also assumes lexical decomposition. Pustejovsky's lexical decomposition makes use of factual or encyclopedic knowledge in a rigorous formalism called the *qualia* structure. The qualia structure of *book*, for instance, expresses such factual knowledge as the origin of *book* as *write(x, y)* in the Agentive quale, where *x* is a writer (i.e., *human(x)*), and *y* is a book (i.e., *book(y)*). The qualia structure also expresses the use of the word in the Telic quale; hence, the lexical semantic structure for *book* includes such factual knowledge as *read(w, y)*, where *w* is a reader (i.e., *human(w)*), and *y* is a book.

The factual or encyclopedic knowledge is not only expressed in formal linguistic representations but also plays a crucial role in explaining a significant portion of linguistic phenomena. We interpret (24) as either *Chomsky began writing a book* or *Chomsky began reading a book*. Pustejovsky suggests generative devices like type coercion and co-composition to explain the two readings of (24) in a formal theory; i.e., *writing* or *reading* is part of the qualia structure of *book*, and, hence, the two readings of (24) are predicted by formal principles of lexical semantics.

(24) Chomsky began a book.

It is far beyond the scope of this article to discuss the GL theory in detail. But the success of the GL theory for a vast range of empirical data shows that the boundary between *semantic* and *encyclopedic* or between *linguistic* and *nonlinguistic* is not so clear as B&S assume in their distinction between CS and SF.

Suggested Readings

For a quick overview of conceptual semantics with one paper, see Jackendoff (1987a). For foundational issues of conceptual semantics, see Jackendoff (1983). For an overview of language and other cognitive capacities from a broad perspective, see Jackendoff (1987c). Jackendoff (1990) offers a comprehensive picture of conceptual semantics. Jackendoff (1997) is a bit technical, but it is important to set up the parallel architecture of language. For syntactic issues of conceptual semantics, see Jun (2003) and Culicover and Jackendoff (2005).

Lexical Conditions

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

In many schools of linguistics it is assumed that each sentence *S* in a natural language has a so-called *semantic analysis* (SA), a syntactic structure representing *S* in such a way that the meaning of *S* can be read off its SA in a regular way. The SA of a sentence *S* is distinct from its *surface structure* (SS), which corresponds directly with the way *S* is to be pronounced. Each language has a set of rules, its grammar **G**, defining the relationship between the SAs and the SSs of its sentences. The SA of a sentence *S* is often also called its *logical form*, because the SA exhibits not only the predicate-argument structure of *S* and its embedded clauses if *S* has any, but also the logically correct position of tense, quantifiers, negation, modalities, and other possible operators – besides all the meaningful lexical items of the corresponding SS. SAs are thus analytical as regards their structure, not as regards their lexical items. The lexical items of SSs are in place in SAs: in principle, SAs provide an analysis that goes as far as the lexical items and stops there. SAs do not specify lexical meanings.

Lexical meanings are normally specified in dictionaries, but dictionaries do so from an SS point of view. However, linguistic theories assuming an SA-level of representation for sentences require that lexical meanings be specified at SA-level. The difference is that, at SA-level, lexical items are allowed to occur only in predicate positions. A surface sentence like (1a) is represented at SA-level as (1b), written as the linear formula (1c) and read intuitively as (1d):

(1a) The farmer was not working on the land.
(1b)

(1c) S[V[not] S[V[past] S[V[on] S[V[be] S[V[work] NP[the y S[V[farmer] NP[y]]]]] NP[the x S[V[land] NP[x]]]]]]
(1d) It is not so that in the past on the land the farmer was working.

The items *not*, *past*, *on*, *be–ing*, *work*, *farmer*, and *land* are all labeled 'V', which makes them predicates in (1b). In (1a), however, *farmer* is a noun, the past tense is incorporated into the finite verb form *was*, *not* is usually considered an adverb, *working* is a present participle in the paradigm of the verb *work*, *on* is a preposition, and *land* is again a noun.

Lexical Conditions

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

In many schools of linguistics it is assumed that each sentence *S* in a natural language has a so-called *semantic analysis* (SA), a syntactic structure representing *S* in such a way that the meaning of *S* can be read off its SA in a regular way. The SA of a sentence *S* is distinct from its *surface structure* (SS), which corresponds directly with the way *S* is to be pronounced. Each language has a set of rules, its grammar **G**, defining the relationship between the SAs and the SSs of its sentences. The SA of a sentence *S* is often also called its *logical form*, because the SA exhibits not only the predicate-argument structure of *S* and its embedded clauses if *S* has any, but also the logically correct position of tense, quantifiers, negation, modalities, and other possible operators – besides all the meaningful lexical items of the corresponding SS. SAs are thus analytical as regards their structure, not as regards their lexical items. The lexical items of SSs are in place in SAs: in principle, SAs provide an analysis that goes as far as the lexical items and stops there. SAs do not specify lexical meanings.

Lexical meanings are normally specified in dictionaries, but dictionaries do so from an SS point of view. However, linguistic theories assuming an SA-level of representation for sentences require that lexical meanings be specified at SA-level. The difference is that, at SA-level, lexical items are allowed to occur only in predicate positions. A surface sentence like (1a) is represented at SA-level as (1b), written as the linear formula (1c) and read intuitively as (1d):

(1a) The farmer was not working on the land.
(1b)

(1c) S[V[not] S[V[past] S[V[on] S[V[be] S[V[work] NP[the y S[V[farmer] NP[y]]]]] NP[the x S[V[land] NP[x]]]]]]
(1d) It is not so that in the past on the land the farmer was working.

The items *not*, *past*, *on*, *be–ing*, *work*, *farmer*, and *land* are all labeled 'V', which makes them predicates in (1b). In (1a), however, *farmer* is a noun, the past tense is incorporated into the finite verb form *was*, *not* is usually considered an adverb, *working* is a present participle in the paradigm of the verb *work*, *on* is a preposition, and *land* is again a noun.

Because predicates express properties, the question is what property the predicates at issue assign to what kind of objects. *Not* assigns the property of being false to the proposition in its scope. (Finnish and cognate languages use verbs for the negation: 'John *nots* working' for 'John does not work.') *Past* places its proposition in a given past time. *On* says that the farmer's being at work is on the land. (Some American Indian languages say 'the farmer's working *on-s* the land,' with *on* as a verb.) *Be–ing* stretches the farmer's working out over a period of time. *Farmer* and *land* assign the property of being a farmer, or land, to the values of their variables. Thus, despite differences in surface categories, all lexical words can be regarded as predicates at SA level.

Analyzing all lexical meanings as predicate meanings has the advantage of a uniform format of lexical specification for all lexical items. The format is that of a definition of *satisfaction conditions* or *lexical conditions*. The lexical conditions of an *n*-ary predicate P^n define the property assigned by P^n. They are the conditions that must be fulfilled by any object (or *n*- tuple of objects) *o* for *o* to deserve P^n, in the sense that when P^n is applied to *o*, a true proposition results. Thus, for example, the conditions that determine whether a sentence like *This animal is a dog* is true are the lexical conditions associated with the predicate *dog*, applied to whatever object is referred to by the definite term *this animal*. Only if that object fulfills the conditions that are necessary for doghood is the sentence true. Generally, the *extension* $[[P^n]]$ of the predicate P^n is the set of *n*- tuples of world objects *o* that fulfill the conditions set for P^n. Or:

(1) $[[P^n]] = \{<o_1, \ldots, o_n> \mid \ldots \text{(lexical conditions)} \ldots\}$

It is important to note that the lexical conditions thus specified do not, generally, exhaust the meaning of a predicate, even though lexical conditions can be formulated with great subtlety. Meanings often have *vague* boundaries, which makes the formulation of lexical conditions difficult. Words are often *polysemous* in that they have different but related meanings, such as the word *chest*, which applies either to a box meant for storage or to the part of a human body that is enclosed by the ribs. Polysemy often leads to homonymy or near homonymy (again with vague boundaries), as in the case of *table* (piece of furniture, slab of stone with symbols on it, or well-ordered list of data) or *leaf* (of a tree or of a book). Moreover, there is often *dynamic filtering* in word meanings, as in *The office is on fire* versus *The office has a day off*. In the former, the term *the office* denotes a building, in the latter a group of employees. The difference is caused by the nature of the predicate: *be on fire* requires a combustible object, whereas *have a day off* requires humans under a statute imposing duties, but how to integrate such possible referential differences into the format shown in (1) is unknown (and largely undiscussed in the literature). Then there is *object dependency*, as with verbs of cutting: one *cuts* the grass, one's hair or nails, one's finger, and the meat (though cutting one's finger is very different from cutting the meat); one *trims* the hedge and the dog, and sometimes one's hair also; one *tailors* a suit (German: *schneiden*); one *gelds* a horse (French: *couper*), etc. It is such phenomena that make it hard to use the format shown in (1) for the practical purposes of dictionaries.

In one respect, the format of (1) can be refined. Presuppositions are naturally accounted for by making a distinction between two kinds of lexical conditions, *preconditions* and *update conditions* (*see* **Presupposition**). Presuppositions are derivable from the preconditions of SA-predicates (see Fillmore, 1971; Seuren, 1985: 266–313). Consider the predicate *be divorced*. For someone to be divorced, they must have been married first. Or the predicate *be back*: for someone to be back, they must have been away first. The conditions of having been married first or having been away first are the preconditions of these predicates. The condition that the marriage has been dissolved, or that the person in question is no longer away, is the update condition.

When a precondition is not fulfilled, the sentence suffers from presupposition failure, a condition that, according to some (in particular Strawson, 1950), leads to a lack of truth value and according to others (Blau, 1978; Seuren, 1985), to a third truth value, strong or 'radical' falsity. If an update condition is not fulfilled, the sentence is simply, or minimally, false. In presupposition theory, the lexical conditions of a predicate P^n can thus be presented in the following general format:

(2) $[[P^n]] = \{<o1, \ldots, on> : \ldots \text{(preconditions)} \ldots \mid \ldots \text{(update conditions)} \ldots\}$

This format is exemplified in, for example, the following specification for *be divorced*:

(3) $[[\text{be divorced}^1]] = \{ o : o \text{ was married} \mid o\text{'s marriage has been legally dissolved} \}$

Or: 'the extension of the predicate *be divorced* is the set of entities *o* such that *o* (precondition) was married, and (update condition) *o*'s marriage has been legally dissolved'.

Lexical Fields

P Lutzeier, University of Surrey, Surrey, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Lexical fields have an immediate intuitive appeal. The reference to one or two examples like the field of verbs of motion *walk*, *run*, *skip*, ... or the field of adjectives of emotion *happy, angry, disappointed*, ... normally is enough to give the feeling that one knows what we are talking about. A widespread curiosity about words also helps, not the least in the context of being a parent and trying to collect the child's first words. At the same time, one cannot help noticing that textbooks very rarely go beyond the mere mentioning of lexical fields in form of a few examples, plus perhaps some critical remarks about the apparent lack of rigor around the concept. In other words, the intuitive strength of the concept may go together with some theoretical vagueness. Nonetheless, what remains at this stage is the widespread appeal of the concept and undoubtedly successful application of the concept in several disciplines:

- Lexicology, Semantics and Cognitive Linguistics. Lexical fields are a useful tool for holistic approaches about lexical meaning, structures of the vocabulary and mental lexicon as well as issues around categorization.
- Lexicography. The codification of the vocabulary of a language can be done in several different formats, and the organization of entries around lexical fields is one of them and leads to specialized dictionaries.
- Psycholinguistics. Lexical fields are employed in connection with word memory tests, explorations on language acquisition and language loss.
- Anthropology. Lexical fields are a useful tool in fieldwork on the language and culture of societies. This remains a major area in the context of globalization and 'Global' English, and the concern about endangered languages.
- Medical Neuroscience and Clinical Linguistics. Lexical fields are used for the investigation of different forms of aphasia.

In addition to the term 'lexical field,' there are other terms in use, such as 'word field' and 'semantic field'; but we shall confine ourselves to lexical field, which provides greater flexibility, because, in contrast to word field, it implies that the relevant groupings involve lexical elements and these are not necessarily confined to words. At least in theory idioms can be contemplated as possible members of such groupings. We also prefer lexical to semantic because the relevant groupings are parts of the lexicon, and its elements will consist of a form level as well as of a content level.

Background

Lexical fields contribute to structuring the lexicon and to exploration of lexical meaning. Although the lexical meaning of any member of the lexicon must be seen as a holistic entity, this does not preclude its conception as something internally structured. This structure must make provision for phenomena such as monosemy and polysemy; and, for each individual sense, phenomena such as prototypicality, stereotypes, and family resemblances need to be incorporated. In addition, the outer boundaries of the lexical meaning/senses of any member of the lexicon will be established by finding its unique position in the content plane of the lexicon. This happens in contradistinction to other similar lexical meanings along the paradigmatic dimension and in connection with other different, but compatible lexical meanings along the syntagmatic dimension. The paradigmatic dimension is mainly captured by membership in the same lexical fields and by means of sense relations, but also partly by associations. The syntagmatic dimension is mainly captured by collocations, but also partly by associations.

Whichever structure one adopts for the lexical meaning, it cannot be a static one. One has to take

Introduction

Lexical fields have an immediate intuitive appeal. The reference to one or two examples like the field of verbs of motion *walk*, *run*, *skip*, ... or the field of adjectives of emotion *happy, angry, disappointed*, ... normally is enough to give the feeling that one knows what we are talking about. A widespread curiosity about words also helps, not the least in the context of being a parent and trying to collect the child's first words. At the same time, one cannot help noticing that textbooks very rarely go beyond the mere mentioning of lexical fields in form of a few examples, plus perhaps some critical remarks about the apparent lack of rigor around the concept. In other words, the intuitive strength of the concept may go together with some theoretical vagueness. Nonetheless, what remains at this stage is the widespread appeal of the concept and undoubtedly successful application of the concept in several disciplines:

- Lexicology, Semantics and Cognitive Linguistics. Lexical fields are a useful tool for holistic approaches about lexical meaning, structures of the vocabulary and mental lexicon as well as issues around categorization.
- Lexicography. The codification of the vocabulary of a language can be done in several different formats, and the organization of entries around lexical fields is one of them and leads to specialized dictionaries.
- Psycholinguistics. Lexical fields are employed in connection with word memory tests, explorations on language acquisition and language loss.
- Anthropology. Lexical fields are a useful tool in fieldwork on the language and culture of societies. This remains a major area in the context of globalization and 'Global' English, and the concern about endangered languages.
- Medical Neuroscience and Clinical Linguistics. Lexical fields are used for the investigation of different forms of aphasia.

In addition to the term 'lexical field,' there are other terms in use, such as 'word field' and 'semantic field'; but we shall confine ourselves to lexical field, which provides greater flexibility, because, in contrast to word field, it implies that the relevant groupings involve lexical elements and these are not necessarily confined to words. At least in theory idioms can be contemplated as possible members of such groupings. We also prefer lexical to semantic because the relevant groupings are parts of the lexicon, and its elements will consist of a form level as well as of a content level.

Background

Lexical fields contribute to structuring the lexicon and to exploration of lexical meaning. Although the lexical meaning of any member of the lexicon must be seen as a holistic entity, this does not preclude its conception as something internally structured. This structure must make provision for phenomena such as monosemy and polysemy; and, for each individual sense, phenomena such as prototypicality, stereotypes, and family resemblances need to be incorporated. In addition, the outer boundaries of the lexical meaning/senses of any member of the lexicon will be established by finding its unique position in the content plane of the lexicon. This happens in contradistinction to other similar lexical meanings along the paradigmatic dimension and in connection with other different, but compatible lexical meanings along the syntagmatic dimension. The paradigmatic dimension is mainly captured by membership in the same lexical fields and by means of sense relations, but also partly by associations. The syntagmatic dimension is mainly captured by collocations, but also partly by associations.

Whichever structure one adopts for the lexical meaning, it cannot be a static one. One has to take

into account the dynamics of the lexicon, which expresses itself at the synchronic level in form of variation and at the diachronic level in form of change. Such a fascinating complexity of the lexicon of any natural language allows for many different ways of ordering the lexicon, and any particular way of doing so can only capture certain aspects of such a complex system of systems. In a sense, lexical fields themselves have to find their own unique position in the vast field of all possible orderings of the lexicon, and will, in any case, only be able to catch one particular type of ordering. Therefore, stretching and extending the concept beyond its established conception will have to be looked at carefully and may not be the right way forward, especially when we have other concepts such as word families and frames.

The Concept of Lexical Field

Any concept of lexical fields will try to capture the following basic ideas and principles:

- Fields have a position somewhere between the individual lexical element and the whole lexicon, i.e., fields build relevant parts of the lexicon and make a contribution to the structuring of the lexicon.
- Fields and individual words have in common that they are part of the lexicon. Fields and the lexicon have in common that they are constituted from words.
- Fields are (higher level) signs and therefore comprise a form level as well as a content level.
- Each element of the field receives its position in contradistinction and interconnection with other elements of the field. In other words, fields help to establish the senses of individual elements and therefore have to be seen as part of a semasiological approach.
- Each lexical field deals with a particular conceptual domain and therefore can be seen as part of an onomasiological approach.

With regard to the form level of a lexical field, lexical fields are particular paradigmatic groupings within the lexicon, i.e., their elements belong in each case to the same parts of speech. Although examples of lexical fields can be found for any part of speech, the most useful ones in terms of size and structures are found for nouns, verbs, and adjectives. Apart from possible problems with classification in terms of parts of speech, this does not preclude idioms as special lexical elements from being members of lexical fields. Because there are other groupings such as word families and frames that allow links between members from different parts of speech, there is no problem in keeping lexical fields to elements of one and the same part of speech. The fact that we see lexical fields as 'particular' paradigmatic groupings will have to do with the way that the form level is linked to the content level.

If it is true that each lexical field is meant to deal with a particular conceptual domain, then all members of a lexical field will have to relate to this particular domain and therefore will all be similar in terms of their senses. The domain will normally be labeled by a specific term such as 'body part,' 'fruit,' 'transfer,' 'temperature,' etc., and this allows us to talk of 'the lexical field of body part nouns,' 'the lexical field of nouns of fruit,' 'the lexical field of verbs of transfer,' 'the lexical field of adjectives of temperature,' etc. The term that captures the domain provides the semantic framework for the lexical field and each member of this specific field must have a sense that is compatible with the meaning of the domain term, i.e., has an identical to or a more specific sense than the meaning of the term. This way a lexical field also constitutes a special onomasiological grouping, namely all members belong to the same part of speech. This may well mean that the field does not have a member whose sense is identical with the meaning of the domain term. For instance, in the field of English adjectives of temperature, we do not have an adjective that would match the meaning of the noun 'temperature.'

The membership of a lexical field structures the given domain and one needs some tools to describe the particular structure. The resulting description should guarantee the unique position in some kind of semantic space for each member of the lexical field. It is wise to apply a combination of dimensions and sense relations.

The idea is to attach a finite number of dimensions to the field. Each dimension is meant to provide a partition of the whole set. The resulting sets are therefore disjoint with each other and the name of each set normally reflects a necessary part of the relevant sense of the element. In other words, a paraphrase of the relevant sense of the element would normally involve the partition name. It has to be stressed that the idea of such a name is similar, but not identical, to traditional features of a componential analysis and that we are talking metalinguistically of a partition of the set of elements, not of anything out there in reality. For instance, take the trivial paradigm P = {*Venus, morning star, evening star*}. All three nouns refer to the same entity: Venus. In line with Frege's thoughts we could establish a dimension 'Time of occurrence in the sky.' This dimension

would divide the paradigm into three sets: S1 = {*morning star*}, S2 = {*evening star*}, S3 = {*Venus*} with the corresponding names N1 = 'the brightest star in the morning sky,' N2 = 'the brightest star in the evening sky,' N3 = 'neutral.' Furthermore, there is no claim to the effect that the sum of all names of all sets of which a particular element is member of would constitute its sense in respect to the given domain. Also, paraphrases may vary accounts for the dynamic element of any description and therefore one cannot necessarily expect a unique set of dimensions for the description of the lexical field. This does not constitute a weakness of the notion but reflects an important phenomenon of natural language in general. Guiding principles for the choice amongst possible candidates are: (1) those dimensions are preferable that result in sets with several members, and (2) those dimensions are preferable that result in cross-classification.

The familiar tool of sense relations can act as a complement to the tool of dimensions. As far as lexical fields are concerned, the hyponymy-relation and the incompatibility-relation tend to be the most useful ones. The analysis of the field is successful and complete when the net of links by means of these sense relations, always relative to the given domain, plus the relevant names constitute a unique position for each member of the field. An obvious exception is the case of synonyms with regard to the given domain.

The interplay between dimensions and sense relations in forming the semantic space helps in several ways. It frees us from the often difficult task of expressing the unique position by means of an explicit link to necessary parts of the sense, whereas sense relations can often make a valuable contribution by means of more implicit links. The reliance on sense relations also allows an elegant solution to the supposedly thorny problem of completeness for lexical fields. How can you decide whether a particular element should be a member of the field or not? There is an obvious answer in terms of the sense relations: completeness is achieved once one has closure in terms of the sense relations relative to the given domain.

Earlier on, we stressed that the senses of a lexical element will be defined through paradigmatic and syntagmatic links. In other words, it must be accepted that lexical fields as paradigmatic groupings can in most cases only make a partial contribution to the senses of their members. This again is an acknowledgment of the richness of the lexicon of any natural language rather than the admission of a weakness in the concept of lexical field.

Relevance of Lexical Fields

In the 1930s, Jost Trier as the true founder of lexical field theory evoked for lexical fields the idea of a mosaic within the content plane. This idea was discredited in the 1960s and 1970s because of its unfortunate link with Aristotelian/structuralist ideas of categories. As soon as this link was shown not to be a necessary one and lexical fields were taken to be groupings of the kind described here, the old idea of a mosaic could gain new strength again. In this context, lexical field theory can make the legitimate claim to be a forerunner of Cognitive Linguistics.

Many syntactic and semantic theories and concepts come and go. Against this pattern, lexical field theory and the concept of lexical field has proven to be remarkably stable. What is urgently needed is the will to engage in more practical descriptions of vast lexical fields across several languages, because such information would provide useful data for typological comparisons across different languages and cultures.

Lexical fields are also witness to the fact that natural languages exist and change as a result of dynamic (field) forces. It goes without saying that any linguistic theory worthy of its name must take account of such changes and therefore cannot afford to ignore the concept of lexical field.

Lexical Functional Grammar

M Dalrymple, Oxford University, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

LFG's Syntactic Structures

Lexical Functional Grammar (LFG) is a theory of the structure of language and how different aspects of linguistic structure are related. As the name implies, the theory is lexical; the lexicon is richly structured, with lexical relations rather than transformations or operations on phrase structure trees as a means of capturing linguistic generalizations. It is also functional; grammatical functions such as subject and object are primitives of the theory, not defined in terms of phrase structure configuration or semantic roles.

LFG assumes that two syntactic levels are important in the analysis of linguistic structure. F(unctional)-structure represents abstract grammatical functions such as subject and object as well as abstract features such as tense and case. Another level, c(onstituent)-structure, represents the concrete phrasal expression of these relations, governed by language-particular constraints on word order and phrase structure. This duality of syntactic representation is motivated by the different natures of these two structures both within and across languages. Languages vary greatly in word order and phrasal structure, and the theory of constituent structure allows for this variation within certain universally defined parameters. In contrast, all languages share the same functional vocabulary. According to LFG's theory of functional structure, the abstract syntactic structure of every language is organized in terms of subject, object, and other grammatical functions, most of which are familiar from traditional grammatical work.

Regularities in the relation between c-structure and f-structure are captured by functions relating parts of one structure to parts of the other. For example, the subject phrase in the c-structure tree is related to the subject f-structure by means of a function that relates nodes of the c-structure tree to parts of the f-structure for a sentence. Relations among c-structure, f-structure, and other linguistic levels have also been explored and defined in terms of functional mappings from subparts of one structure to the corresponding subparts of other structures.

The overall formal structure and basic linguistic assumptions of the theory have changed very little since its development in the late 1970s by Joan Bresnan, a linguist trained at the Massachusetts Institute of Technology, and Ronald M. Kaplan, a psycholinguist and computational linguist trained at Harvard University. Bresnan (1982) is a collection of influential early papers in LFG; recent works providing an overview or introduction to LFG include Dalrymple *et al.* (1995), Bresnan (2001), Dalrymple (2001), Falk (2001), and Kroeger (2004).

Constituent Structure

Languages vary greatly in the basic phrasal expression of even simple sentences. Basic word order can be verb-initial (Malagasy), verb-final (Japanese), or verb-medial (English). Word order correlates with grammatical function in some languages, such as

Lexical Functional Grammar

LFG's Syntactic Structures

Lexical Functional Grammar (LFG) is a theory of the structure of language and how different aspects of linguistic structure are related. As the name implies, the theory is lexical; the lexicon is richly structured, with lexical relations rather than transformations or operations on phrase structure trees as a means of capturing linguistic generalizations. It is also functional; grammatical functions such as subject and object are primitives of the theory, not defined in terms of phrase structure configuration or semantic roles.

LFG assumes that two syntactic levels are important in the analysis of linguistic structure. F(unctional)-structure represents abstract grammatical functions such as subject and object as well as abstract features such as tense and case. Another level, c(onstituent)-structure, represents the concrete phrasal expression of these relations, governed by language-particular constraints on word order and phrase structure. This duality of syntactic representation is motivated by the different natures of these two structures both within and across languages. Languages vary greatly in word order and phrasal structure, and the theory of constituent structure allows for this variation within certain universally defined parameters. In contrast, all languages share the same functional vocabulary. According to LFG's theory of functional structure, the abstract syntactic structure of every language is organized in terms of subject, object, and other grammatical functions, most of which are familiar from traditional grammatical work.

Regularities in the relation between c-structure and f-structure are captured by functions relating parts of one structure to parts of the other. For example, the subject phrase in the c-structure tree is related to the subject f-structure by means of a function that relates nodes of the c-structure tree to parts of the f-structure for a sentence. Relations among c-structure, f-structure, and other linguistic levels have also been explored and defined in terms of functional mappings from subparts of one structure to the corresponding subparts of other structures.

The overall formal structure and basic linguistic assumptions of the theory have changed very little since its development in the late 1970s by Joan Bresnan, a linguist trained at the Massachusetts Institute of Technology, and Ronald M. Kaplan, a psycholinguist and computational linguist trained at Harvard University. Bresnan (1982) is a collection of influential early papers in LFG; recent works providing an overview or introduction to LFG include Dalrymple *et al.* (1995), Bresnan (2001), Dalrymple (2001), Falk (2001), and Kroeger (2004).

Constituent Structure

Languages vary greatly in the basic phrasal expression of even simple sentences. Basic word order can be verb-initial (Malagasy), verb-final (Japanese), or verb-medial (English). Word order correlates with grammatical function in some languages, such as

English, in which the subject and other arguments appear in particular phrase structure positions. In other languages, word order is more free, and grammatical functions are identified by case marking or agreement rather than phrasal configuration; in many languages, there is no specific phrasal position where the subject or object must always appear. Requirements for phrasal groupings also differ across languages. In English, for example, a noun and any adjectives that modify it must appear together and form a phrasal unit. In many other languages, including Latin, this is not necessary and a noun can be separated from its modifying adjectives in the sentence. LFG's constituent structure represents word order and phrasal constituenthood.

Constituent Structure Representation

Like many other linguistic theories, LFG represents word order and phrasal groupings by means of phrase structure trees, also called constituent structures (*see* **Constituent Structure**) or c-structures. The c-structure for an English sentence such as *David is sleeping* is:

(1) David is sleeping.

C-structure trees contain two sorts of categories. Categories such as N (noun) and V (verb), familiar from traditional grammatical analysis, are called lexical categories. Most LFG analyses assume at least the lexical categories N (noun), A (adjective), V (verb), Adv (adverb), and P (preposition), although more or fewer categories may be relevant for a particular language. Most languages also make use of a set of functional categories, including I (for Inflection), C (for Complementizer), and D (for Determiner). Functional categories play an organizing role in the syntax and are either associated with closed-class categories such as complementizers or are filled with subtypes of particular lexical categories.

Constituent structure is organized according to X-bar theory (*see* **X-Bar Theory**), which assumes that phrases are internally headed and therefore endocentric; a phrase and its head have the same category but a different bar level. For example, the basic lexical category N is the head of the single-bar-level category N′ ('N-bar'), which in turn is the head of the two-bar-level category N″ ('N-double-bar'). Similarly, the basic functional category I is the head of I′, which heads I″. Many LFG analyses assume that N″ and I″ are maximal phrases, meaning that there is no category N‴ or I‴ for the double-bar-level category to head. Thus, as maximal phrases, the categories N″ and I″ are usually written as NP (noun phrase) and IP (the category assigned to a sentence such as *David is sleeping*). Nonprojecting categories are also assumed (Toivonen, 2003); these are lexical categories that are not heads of phrases but appear on their own, adjoined to heads. For example, verbal particles (words corresponding to the particle *up* in a sentence such as *I woke up the baby*) in some Germanic languages are nonprojecting words, typically prepositions, adjoined to the verb.

Not all phrases are endocentric. LFG assumes a single exocentric, nonheaded category, the category S, which does not obey the constraints of X-bar theory. Not all languages make use of this phrase; it plays no role in the syntax of English, for example. In languages that make use of this phrase, it behaves as a maximal phrase, but it has no c-structure head and it can dominate phrases of any category or bar level.

A phrase can dominate other constituents in addition to its head. LFG does not require phrase structure trees to be binary branching, and so there can be more than two daughters of any node in a c-structure tree. The nonhead daughter of a maximal phrase is called its specifier, and the nonhead sisters of a lexical category are its complements. This is shown schematically in (2).

(2)

As shown in (1), a verbal category, often an auxiliary, appears in I. The complement of I is either VP, as in (1), or, in languages that make use of it, the exocentric category S. Not all languages make use of the functional category C and the phrases it heads, C′ and CP. When a language makes use of this category, complementizers or verbs can appear in C, and the complement of C is IP or S. The functional category D, filled by a determiner, is also often assumed; the complement of D is NP. In the following, we do not assume DP, which means that the category of a phrase such as *the boy* is NP. However, there is no general agreement of the status of such phrases in LFG. According to some analyses, *the boy* is a DP rather than an NP in at least some languages.

Unlike many theories, LFG assumes that daughters of all phrasal categories are optional. In particular, the head of a maximal phrase need not appear. In many languages, for example, tensed verbs appear in I (King, 1995; Sells, 2001). A Swedish sentence such as (3), with a tensed verb and no nontensed verbs, has a VP that does not contain a V.

(3) Anna såg boken
Anna saw book.DEF
'Anna saw the book.'

Nonhead daughters are also only optionally present. In Japanese and other so-called 'prodrop' languages, a verb can appear with no overt arguments. If no overt arguments of a verb are present, the c-structure tree contains only the verb:

(4) koware-ta
break-PAST
'[it/something] broke.'

C-structure does not contain subparts of words or unpronounced features, nor does it contain null pronominals in prodrop languages such as Japanese. Rather, it reflects the structure and grouping of the full syntactic units – the words and phrases – in the sentence.

Phrase Structure Rules

LFG draws a strong distinction between the formal objects of the theory – constituent structure trees and functional structures – and the constraints or descriptions involving those objects. C-structure trees are constrained by phrase structure rules, which license local tree configurations. The phrase structure rule in (5a) licenses the c-structure in (5b):

(5a) IP → NP I′

(5b)

The right-hand side of an LFG phrase structure rule is a regular expression, allowing for disjunction, optionality, and arbitrary repetition of a node or sequence of nodes. The V and NP daughters in the rule in (6) are optional, and the Kleene star (*) annotation on the PP indicates that a sequence of zero or more PP constituents may appear.

(6) V′ → (V) (NP) PP*

Functional Structure

Syntactic analyses in traditional grammatical descriptions are stated in terms of abstract syntactic functions such as subject, object, and complement. These functions are represented at LFG's functional structure. F-structure represents abstract grammatical functions such as subject and object, as well as features such as tense, case, person, and number.

Grammatical Functions and Their Representation

In a sentence such as *David devoured a sandwich, David* is the subject and *a sandwich* is the object. This information is represented by an attribute-value structure, the f-structure, in which the value of the SUBJ feature is the f-structure for the subject and the value of the OBJ feature is the f-structure for the object.

(7) David devoured a sandwich.

$$\begin{bmatrix} \text{PRED} & \text{'DEVOUR}\langle\text{SUBJ, OBJ}\rangle\text{'} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{'DAVID'} \end{bmatrix} \\ \text{OBJ'} & \begin{bmatrix} \text{SPEC} & \text{A} \\ \text{PRED} & \text{'SANDWICH'} \end{bmatrix} \end{bmatrix}$$

For clarity, many of the features and values in this f-structure have been omitted, a practice often followed in LFG presentations. The full f-structure contains tense, aspect, person, number, and other functional features.

Every content word in a sentence contributes a value for the feature PRED. These values are called semantic forms. In the functional structure, semantic forms are surrounded by single quotes: the semantic form contributed by the word *David* is 'DAVID.'

An important property of semantic forms is that they are uniquely instantiated for each instance of their use, reflecting the unique semantic contribution of each word within the sentence. This is occasionally

indicated by associating a unique numerical identifier with each instance of a semantic form, as in (8):

(8) David devoured a sandwich.

$$\begin{bmatrix} \text{PRED} & \text{`DEVOUR}_{37}\langle\text{SUBJ,OBJ}\rangle\text{'} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{`DAVID}_{42}\text{'} \end{bmatrix} \\ \text{OBJ} & \begin{bmatrix} \text{SPEC} & \text{A} \\ \text{PRED} & \text{`SANDWICH}_{14}\text{'} \end{bmatrix} \end{bmatrix}$$

In (8), the particular occurrence of the semantic form for the word *David* as it is used in this sentence is represented as 'DAVID$_{42}$.' Another use of *David* will be associated with a different unique identifier, perhaps 'DAVID$_{73}$.' Representing semantic forms with explicit numerical identifiers clearly shows that each word makes a unique contribution to the f-structure. However, the identifiers also add unnecessary clutter to the f-structure and, therefore, are usually not displayed.

A verb or other predicate generally requires a particular set of arguments: for example, the verb *devoured* requires a subject (SUBJ) and an object (OBJ). These arguments are said to be governed by the predicate; equivalently, the predicate is said to subcategorize for its arguments. The semantic form contributed by a verb or other predicate contains information about the arguments it governs. As shown in (8), the governed arguments appear in angled brackets: 'DEVOUR⟨SUBJ,OBJ⟩.'

The LFG requirements of completeness and coherence ensure that all and only the grammatical functions governed by a predicate are found in the structure of a grammatically acceptable sentence. For example, the unacceptability of example (9) shows that the verb *devoured* cannot appear without an OBJ:

(9) *David devoured.

This sentence violates the principle of completeness, according to which every grammatical function governed by a predicate must be filled. Here, the OBJ is not present, and the sentence is incomplete.

Furthermore, *devour* cannot appear with other functions than the grammatical functions SUBJ and OBJ that it governs. Example (10) shows that it cannot appear with a sentential complement in addition to its object:

(10) *David devoured a sandwich that it was raining.

This sentence violates the principle of coherence, according to which only the grammatical functions that are governed by a predicate can appear. Because the sentence contains a grammatical function that the verb *devour* does not govern, it is incoherent.

Table 1 Governable grammatical functions

SUBJ	Subject
OBJ	Object
COMP	Sentential or closed (nonpredicative) infinitival complement
XCOMP	An open (predicative) complement, often infinitival, whose SUBJ function is externally controlled
OBJ$_\theta$	A family of secondary OBJ functions associated with a particular, language-specific set of thematic roles; in English, only OBJ$_{\text{THEME}}$ is allowed, while other languages allow more than one thematically restricted secondary object
OBL$_\theta$	A family of thematically restricted oblique functions such as OBL$_{\text{GOAL}}$ or OBL$_{\text{AGENT}}$, often corresponding to adpositional phrases at c-structure

The grammatical functions that a predicate can govern are called governable grammatical functions. The inventory of universally available governable grammatical functions is given in Table 1. Languages differ as to which of these functions are relevant, but in many languages, including English, all of these functions are used.

Not all phrases fill argument positions of a predicate. Modifying adjunct phrases are not required by a predicate and hence are not governable. In (11), the phrase *yesterday* bears the nongovernable grammatical function ADJ (unct):

(11) David devoured a sandwich yesterday.

There are two nongovernable grammatical functions. The function ADJ is the grammatical function of modifiers such as *in the park, with a hammer*, and *yesterday*. The function XADJ is the grammatical function of open predicative adjuncts whose subject is externally controlled; as with the governable grammatical function XCOMP, the X in the name of the function indicates that it is an open function whose SUBJ is supplied externally. The phrase filling the XADJ role is in boldface in (12).

(12a) **Having opened the window**, David took a deep breath.
(12b) David ate the celery **naked**.
(12c) David ate the celery **raw**.

In (12a) and (12b), the open adjunct XADJ is controlled by the subject of the main clause: It is David who opened the window, and it is David who is naked. In (12c), the XADJ is controlled by the object: It is the celery that is raw.

Unlike governable grammatical functions, more than one adjunct function can appear in a sentence:

(13) David devoured a sandwich **at noon yesterday**.

Because the ADJ function can be multiply filled, its value is a set of f-structures:

(14) David devoured a sandwich at noon yesterday.

$$\begin{bmatrix} \text{PRED} & \text{'DEVOUR}\ \langle \text{SUBJ,OBJ} \rangle\text{'} \\ \text{SUBJ} & \begin{bmatrix} \text{PRED} & \text{'DAVID'} \end{bmatrix} \\ \text{OBJ} & \begin{bmatrix} \text{SPEC} & \text{A} \\ \text{PRED} & \text{'SANDWICH'} \end{bmatrix} \\ \text{ADJ} & \left\{ \begin{matrix} \begin{bmatrix} \text{PRED} & \text{'YESTERDAY'} \end{bmatrix} \\ \begin{bmatrix} \text{PRED} & \text{'AT}\ \langle \text{OBJ} \rangle\text{'} \\ \text{OBJ} & \begin{bmatrix} \text{PRED} & \text{'NOON'} \end{bmatrix} \end{bmatrix} \end{matrix} \right\} \end{bmatrix}$$

The same is true of XADJ; more than one XADJ phrase can appear in a single sentence:

(15) **Having opened the window**, David ate the celery **naked**.

Hence, the value of the XADJ feature is also a set of f-structures.

The f-structures that have been presented so far have included only a subset of their functional features. In fact, it is common in LFG literature to display only those features that are relevant to the analysis under discussion because a full representation is often too unwieldy. A full f-structure for these sentences contains at least the features and values listed in Table 2 and probably other language-specific features and values as well. The values given in this chart are the ones that are most often assumed, but some authors have argued for a different representation of the values of some features. For example, Dalrymple and Kaplan (2000) argue for a set-based representation of the PERS and GEND features to allow for an account of feature resolution in coordination and of the CASE feature to allow for case indeterminacy. Some studies assume a PCASE feature whose value specifies the grammatical function of its phrase. In more recent work, Nordlinger (1998) provided a theory of constructive case, according to which a case marked phrase places constraints on its f-structure environment that determine its grammatical function in the sentence. This treatment supplants the traditional treatment of obliques in terms of the PCASE feature.

Table 2 f-Structure features

	Feature	*Value*
Person	PERS	1, 2, 3
Gender	GEND	MASC, FEM, . . .
Number	NUM	SG, DUAL, PL, . . .
Case	CASE	NOM, ACC, . . .
Surface form	FORM	Surface word form
Verb form	VFORM	PASTPART, PRESPART, . . .
Complementizer form	COMPFORM	Surface form of complementizer: THAT, WHETHER, . . .
Tense	TENSE	PRES, PAST, . . .
Aspect	ASPECT	F-structure representing complex description of sentential aspect; sometimes abbreviated, e.g., PRES.IMPERFECT
Pronoun type	PRONTYPE	REL, WH, PERS, . . .

Functional Descriptions

As with c-structures, we draw a sharp distinction between f-structures and their descriptions. The set of f-structure constraints associated with the analysis of some sentence is called a functional description or f-description.

To refer to the value of a feature, say, TENSE, in some f-structure, we use an expression like the following:

(16) $(f\ \text{TENSE})$

This expression refers to the value of the TENSE feature in the f-structure f. If we want to specify the value of that feature, we use an expression such as:

(17) $(f\ \text{TENSE}) = \text{PAST}$

This **defining equation** specifies that the feature TENSE in the f-structure f has the value PAST.

We can also specify that an feature has a particular f-structure as its value. The expression in (18) specifies that the value of the SUBJ feature in f is the f-structure g:

(18) $(f\ \text{SUBJ}) = g$

Some features take as their value a set of functional structures. For example, because any number of adjuncts can appear in a sentence, the value of the feature ADJ is a set. We can specify that an f-structure h is a member of the ADJ set with the following constraint, using the set-membership symbol $\in$:

(19) $h \in (f\ \text{ADJ})$

The constraints discussed so far are called defining constraints because they define the required properties of a functional structure. An abbreviated f-description for a sentence such as *David sneezed* is:

(20) $(f\ \text{PRED}) = \text{'SNEEZE}\langle\text{SUBJ}\rangle\text{'}$
$(f\ \text{TENSE}) = \text{PAST}$
$(f\ \text{SUBJ}) = g$
$(g\ \text{PRED}) = \text{'DAVID'}$

This f-description holds of the following f-structure, where the f-structures are annotated with the names used in the f-description (20):

(21) David sneezed

$$f\colon \begin{bmatrix} \text{PRED} & \text{'SNEEZE}\langle\text{SUBJ}\rangle\text{'} \\ \text{TENSE} & \text{PAST} \\ \text{SUBJ} & g\colon \begin{bmatrix} \text{PRED} & \text{'DAVID'} \end{bmatrix} \end{bmatrix}$$

Notice, however, that the f-description also holds of the f-structure in (22), which also contains all the attributes and values that are mentioned in the f-description in (20):

(22)
$$f\colon \begin{bmatrix} \text{PRED} & \text{'SNEEZE}\langle\text{SUBJ}\rangle\text{'} \\ \text{TENSE} & \text{PAST} \\ \text{SUBJ} & g\colon \begin{bmatrix} \text{PRED} & \text{'DAVID'} \\ \text{PERS} & 3 \end{bmatrix} \\ \text{ADJ} & \left\{ \begin{matrix} \begin{bmatrix} \text{PRED} & \text{'YESTERDAY'} \end{bmatrix} \\ \begin{bmatrix} \text{PRED} & \text{'AT}\langle\text{OBJ}\rangle\text{'} \\ \text{OBJ} & \begin{bmatrix} \text{PRED} & \text{'NOON'} \end{bmatrix} \end{bmatrix} \end{matrix} \right\} \end{bmatrix}$$

However, the f-structure in (22) is not the minimal or smallest solution to the f-description in (20) because it contains additional attributes and values that do not appear in the f-description. We require the f-structure solution for a particular f-description to be the minimal solution to the f-description: no additional attributes or values that are not mentioned in the f-description are included. Thus, the correct solution to the f-description in (20) is the f-structure in (21), not the larger one in (22). Formally, the solution to an f-description is the most general f-structure that satisfies the f-description, which subsumes all other (larger) f-structures that satisfy the f-description.

In addition to the defining constraints just described, LFG also allows elements of the f-description to check the properties of the minimal solution to the defining equations. The expression in (23) is a constraining equation, distinguished from a defining equation by the *c* subscript on the equals sign in the expression:

(23) $(f\ \text{SUBJ NUM}) =_c \text{SG}$

When this expression appears, the f-structure *f* that is the minimal solution to the defining equations must contain the feature SUBJ whose value has an feature NUM with value SG. The constraining equation in (23) does not hold of the f-structure in (21) because in that f-structure the value of the NUM feature has been left unspecified and the SUBJ of *f* does not have a NUM feature with value SG.

In contrast, the functional description in (24a) for the sentence *David sneezes* has a well-formed solution, the f-structure in (24b):

(24a) $(f\ \text{PRED}) = \text{'SNEEZE}\langle\text{SUBJ}\rangle\text{'}$
$(f\ \text{TENSE}) = \text{PRES}$
$(f\ \text{SUBJ}) = g$
$(g\ \text{PRED}) = \text{'DAVID'}$
$(g\ \text{NUM}) = \text{SG}$
$(f\ \text{SUBJ NUM}) =_c \text{SG}$

(24b)
$$f\colon \begin{bmatrix} \text{PRED} & \text{'SNEEZE}\langle\text{SUBJ}\rangle\text{'} \\ \text{TENSE} & \text{PRES} \\ \text{SUBJ} & g\colon \begin{bmatrix} \text{PRED} & \text{'DAVID'} \\ \text{NUM} & \text{SG} \end{bmatrix} \end{bmatrix}$$

Here, the value SG for the NUM feature for *g* is specified in the second-to-last line of the functional description. Thus, the f-structure in (24b) satisfies the defining constraints given in the first five lines of (24a). Moreover, it satisfies the constraining equation given in the last line of (24a).

We can also place other requirements on the minimal solution to the defining equations in some f-description. The expression in (25a) requires *f* not to have the value PRESENT for the feature TENSE, which can happen if *f* has no TENSE feature or if *f* has a TENSE feature with some value other than PRESENT. When it appears in a functional description, the expression in (25b) is an existential constraint, requiring *f* to contain the feature TENSE, but not requiring any particular value for this feature. We can also use a negative existential constraint to require an f-structure not to contain an feature, as in (25c), which requires *f* not to contain the feature TENSE with any value whatsoever.

(25a) Negative equation: $(f\ \text{TENSE}) \neq \text{PRESENT}$
(25b) Existential constraint: $(f\ \text{TENSE})$
(25c) Negative existential constraint: $\neg(f\ \text{TENSE})$

Functional descriptions can also be stated in terms of the Boolean operations of conjunction, disjunction, and negation. In the f-descriptions just given, we implicitly assume that the constraints in the f-description are interpreted conjunctively; if an f-description contains more than one requirement, each requirement must hold. LFG also allows disjunctions and negations of sets of requirements. For example, a verb like *sneeze* contributes the following f-description:

(26) sneeze
$$\begin{aligned} &(f\ \text{PRED}) = \text{'SNEEZE}\langle\text{SUBJ}\rangle\text{'} \\ &\{(f\ \text{VFORM}) = \text{BASE} \mid \\ &\ (f\ \text{TENSE}) = \text{PRES} \\ &\ \neg\{(f\ \text{SUBJ PERS}) = 3 \\ &\qquad (f\ \text{SUBJ NUM}) = \text{SG}\}\} \end{aligned}$$

Disjunction is indicated by curly brackets, with the alternatives separated by a vertical bar |. Negation for a set of requirements is represented by prefixing ¬, and the scope of negation is indicated by curly brackets.

This lexical entry allows two possibilities. The first is for the base form of the verb, in which the value of the VFORM feature is BASE. For the second possibility, the value of the feature TENSE is PRES for present tense, and a third-person singular subject is disallowed by negating the possibility for the PERS feature to have value 3 when the NUM feature has value SG.

The Constituent Structure–Functional Structure Relation

There are clear crosslinguistic regularities relating constituent structure positions to grammatical functions. In particular, phrases and their heads are required to correspond to the same f-structure, and specifier and complement positions are associated with particular grammatical functions. Such generalizations constrain the relation between c-structure positions and the f-structure positions they are associated with.

Structural Correspondences

To express these generalizations formally, relating nodes in the c-structure tree and the f-structures they correspond to, we can define a function called ϕ (*phi*) that relates nodes of the c-structure tree to parts of the f-structure for a sentence. In (27), the ϕ function from the NP node to the f-structure it corresponds to is represented by an arrow and labeled ϕ.

(27) David sneezed

Each node of the c-structure tree corresponds to some part of the f-structure. As shown in (28), more than one c-structure node can correspond to the same f-structure (the ϕ function is many to one):

(28)

Further, there can be f-structures that have no corresponding c-structure node (the ϕ function is into). Example (29) shows the c-structure and f-structure for a sentence of Japanese, a prodrop language in which the verb optionally specifies functional information about its subject. When there is no overt subject phrase in the sentence, the information specified by the verb supplies the SUBJ value for the sentence. In (29), because there is no overt subject, all of the information about the subject comes from specifications on the verb, and there is no c-structure node corresponding to the SUBJ f-structure.

(29) koware-ta
break-PAST
'[it/something] broke'

Constituent Structure–Functional Structure Correspondences

The ϕ function is important in stating universally valid relations between c-structure positions and the functional roles associated with them. For example, a phrase and its head always correspond to the same f-structure. Furthermore, the complement of a functional category is an f-structure cohead; the functional head and its complement correspond to the same f-structure. This is shown in (30), where the functional category IP, its heads I′ and I, and its complement VP map to the same f-structure.

(30) David is yawning.

The specifier position of the functional categories IP and CP is filled by a phrase bearing a grammaticized discourse function: SUBJ, TOPIC, or FOCUS. Within these limits, languages can differ as to the particular grammaticized discourse function allowed in each of these positions. In English, as we have seen, the specifier position of IP is filled by the SUBJ.

(31) David yawned.

In Finnish, the specifier of IP is associated with the TOPIC function, and the specifier of CP is associated with FOCUS.

(32) Mikolta Anna sai kukkia.
Mikko Anna got flowers.
'From Mikko, Anna got flowers.'

When a f-structure contains a FOCUS or TOPIC function, the Extended Coherence Condition requires it to be integrated into the f-structure by either anaphorically or functionally binding another f-structure in the sentence. Here, the FOCUS also bears the $\text{OBL}_{\text{SOURCE}}$ function, and the TOPIC is also the SUBJ; these relations involve functional binding because the same f-structure fills both functions. In a sentence such as *Bill, I like him*, the f-structure for *Bill* anaphorically binds the f-structure *him*; the two phrases *Bill* and *him* are syntactically independent and each phrase has its own f-structure, but the anaphoric relation between the two satisfies the Extended Coherence Condition.

The complements of a lexical category bear nondiscourse grammatical functions, that is, any grammatical function other than SUBJ, FOCUS, or TOPIC. In (33), the complements of V are associated with the grammatical functions OBJ and $\text{OBJ}_{\text{THEME}}$.

(33) David gave Chris a book.

Constraining the Constituent Structure–Functional Structure Relation

In describing the relation between c-structure and f-structure, we use the following symbols for the f-structure corresponding to the current node in a phrase structure rule and the f-structure of its mother node:

- the f-structure of the immediately dominating node: ↑
- the f-structure of the current c-structure node: ↓

We can use these symbols to annotate the V′ phrase structure rule with f-structure correspondence constraints.

(34) V′ ⟶ V
↑ = ↓
mother's f-structure = self's f-structure

This annotated rule licenses the configuration in (35). In the c-structure, the V′ node dominates the V node, as the phrase structure rules require. The V′ and V nodes correspond to the same f-structure, as the annotations on the V node require.

(35) V′ → [ ]
|
V

In the rule shown in (36), the V and the V′ node correspond to the same f-structure, as specified by the ↑ = ↓ annotation on the V node. The annotation on the NP node requires the f-structure ↓ corresponding to the NP to be the value of the OBJ value in the f-structure ↑ for the mother node.

(36) V′ ⟶ V NP
↑ = ↓ (↑ OBJ) =↓

The rule in (36) licenses the following configuration:

(37) V′ → [OBJ → [ ]]
V NP

We can use the same formal vocabulary in the specifications of lexical entries. The lexical entry for the verb *sneezed* is shown in (38). It specifies that the c-structure category of *sneezed* is V, and also specifies constraints on the f-structure ↑ of the preterminal V node that dominates the terminal node *sneezed*:

(38) sneezed V (↑ PRED) = 'SNEEZE⟨SUBJ⟩'
(↑ TENSE) = PAST

This lexical entry licenses the c-structure–f-structure configuration in (39).

(39) V → [PRED 'SNEEZE⟨SUBJ⟩'
TENSE PAST]
|
sneezed

Syntax and Semantics

Several recent research strands in LFG have explored the relation of constituent and functional structure

to other linguistic levels. Among these are the theory of the relation between argument structure and syntax, and the 'glue' approach to the interface between syntax and semantics.

Mapping Theory and Argument Linking

Mapping theory explores correlations between the semantic roles of the arguments of a verb and their syntactic functions. If a language assigns the syntactic function SUBJ to the agent argument of an active verb such as *kick*, for example, it invariably assigns SUBJ to the agent argument of semantically similar verbs such as *hit*.

Early formulations of the rules of mapping theory proposed rules relating specific thematic roles to specific grammatical functions, for example, that the thematic role of AGENT is always realized as SUBJ. Later work proposed more general rules relating thematic roles to classes of grammatical functions rather than specific functions. It is most often assumed that grammatical functions are crossclassified with the features ±R and ±O. Several versions of mapping theory have been proposed (Bresnan and Kanerva, 1989; Bresnan and Zaenen, 1990; Bresnan, 2001); in the following, we describe the theory of Bresnan and Zaenen (1990).

The feature ±R distinguishes unrestricted (−R) grammatical functions from restricted (+R) functions. ions. The grammatical functions SUBJ and OBJ are classified as unrestricted, meaning that they can be filled by an argument bearing any thematic role. These contrast with restricted grammatical functions such as obliques or thematically restricted objects, which must be filled by arguments with particular thematic roles; for example, the $\text{OBL}_{\text{SOURCE}}$ function must be filled by an argument bearing the thematic role SOURCE and the thematically restricted object function $\text{OBJ}_{\text{THEME}}$ is filled by a THEME argument.

The feature ±O distinguishes objective (+O) grammatical functions from nonobjective (−O) functions. The unrestricted OBJ function and the restricted OBJ_θ functions are objective, whereas the SUBJ and the oblique functions are nonobjective.

These features crossclassify the grammatical functions as in Table 3. These features are used to state rules of intrinsic classification of particular thematic roles. Such rules constrain the relation between thematic roles and the classes of grammatical functions that these features delineate. For example, arguments bearing the AGENT role are classified as intrinsically nonobjective (−O), either SUBJ or $\text{OBL}_{\text{AGENT}}$. Arguments bearing the THEME role are disjunctively classified, either as intrinsically unrestricted (−R), bearing the SUBJ or OBJ function, or as intrinsically objective (+O), filling the OBJ or $\text{OBJ}_{\text{THEME}}$ function.

Table 3 Classification of grammatical functions

	−R	*+R*
−O	SUBJ	OBL_θ
+O	OBJ	OBJ_θ

In addition to these intrinsic classifications, default mapping rules classify the arguments of a predicate according to their relative position on the thematic hierarchy (Bresnan and Kanerva, 1989):

(40) AGENT > BENEFACTIVE > RECIPIENT/EXPERIENCER > INSTRUMENT > THEME/PATIENT > LOCATIVE

One of the default mapping rules requires the argument of a predicate that is highest on the thematic hierarchy to be classified as unrestricted (−R). For example, if a verb requires an AGENT argument and a PATIENT argument, the AGENT argument thematically outranks the PATIENT argument and, thus, the AGENT argument is classified as unrestricted.

For a predicate with an AGENT and a PATIENT argument, such as *kick*, this has the result in (41) (Bresnan and Kanerva, 1989).

(41)

	kick ⟨ AGENT	PATIENT ⟩
	|	|
intrinsic:	[−0]	[−R]
defaults:	[−R]	
	SUBJ	SUBJ/OBJ
Final classification:	SUBJ	OBJ

For simplicity, we consider only the intrinsically unrestricted classification of the PATIENT argument, leaving aside the option of considering the PATIENT an intrinsically objective function. The AGENT argument is classified as intrinsically nonobjective. The default rules add the unrestricted classification to the thematically highest argument, the AGENT. Because the AGENT is classified as [−O, −R], it is the SUBJ. The unrestricted classification of the PATIENT argument allows it to bear either the SUBJ or the OBJ role, but because the AGENT is assigned the SUBJ role, the PATIENT must be realized as OBJ. Thus, the argument classification rules, together with well-formedness conditions such as the Subject Condition requiring each verbal predicate to have a subject, constrain the mapping between argument roles and grammatical functions.

Glue: The Syntax–Semantics Interface

LFG assumes that the syntactic level that is primarily involved in semantic composition is the functional structure. That is, functional relations such as SUBJ

and OBJ rather than c-structure tree configurations are primarily responsible for determining how the meanings of the parts of a sentence combine to produce the full meaning of the sentence.

The dominant theory of the syntax–semantics interface in LFG is called the glue approach (Dalrymple, 1999, 2001), a theory of how syntax guides the process of semantic composition. The glue approach assumes that each part of the f-structure corresponds to a semantic resource associated with a meaning and that the meaning of an f-structure is obtained by assembling the meanings of its parts according to a set of instructions specifying how the semantic resources can combine. These assembly instructions are provided as a set of logical premises in the 'glue language' of linear logic, and the derivation of a meaning for a sentence corresponds to a logical deduction.

The deduction is performed on the basis of logical premises contributed by the words in the sentence (and possibly by syntactic constructions). Linear logic, a resource-based logic, is used to state requirements on how the meanings of the parts of a sentence can be combined to form the meaning of the sentence as a whole. Linear logic is different from classical logic in that it does not admit rules that allow for premises to be discarded or used more than once in a deduction. Premises in a linear logic deduction are, then, resources that must be accounted for in the course of a deduction; this nicely models the semantic contribution of the words in a sentence, which must contribute exactly once to the meaning of the sentence and may not be ignored or used more than once. A sentence such as *David knocked twice* cannot mean simply *David knocked*; the meaning of *twice* cannot be ignored. It also cannot mean the same thing as *David knocked twice twice*; the meaning of a word in a sentence cannot be used multiple times in forming the meaning of the sentence.

The syntactic structures for the sentence *David yawned*, together with the desired semantic result, are displayed in (42).

(42) David yawned.

The semantic structure for the sentence is related to its f-structure by the correspondence function σ, represented as a dotted line. This result is obtained on the basis of the following lexical information, associated with the verb *yawned*:

(43) $\lambda X.yawn(X)$: $(\uparrow \text{SUBJ})_\sigma \multimap \uparrow_\sigma$

This formula is called a meaning constructor. It pairs the meaning for *yawned*, the one-place predicate $\lambda X.yawn(X)$, with the linear logic formula $(\uparrow \text{SUBJ})_\sigma \multimap \uparrow_\sigma$. In this formula, the connective $\multimap$ is the *linear implication* symbol of linear logic. This symbol expresses a meaning similar to *if* . . . *then*, in this case, stating that if a semantic resource $(\uparrow \text{SUBJ})_\sigma$ representing the meaning of the subject is available, then a semantic resource $\uparrow_\sigma$ representing the meaning of the sentence can be produced. Unlike the implication operator of classical logic, the linear implication operator $\multimap$ carries with it a requirement for consumption and production of semantic resources; the formula $(\uparrow \text{SUBJ})_\sigma \multimap \uparrow_\sigma$ indicates that if a semantic resource $(\uparrow \text{SUBJ})_\sigma$ is found, it is *consumed* and the semantic resource $\uparrow_\sigma$ is produced.

We also assume that a name such as *David* contributes a semantic resource, its semantic structure. In an example like *David yawned*, this resource is consumed by the verb *yawned*, which requires a resource for its SUBJ to produce a resource for the sentence. This accords with the intuition that the verb in a sentence must obtain a meaning for its arguments in order for a meaning for the sentence to be available.

The f-structure for the sentence *David yawned*, together with the instantiated meaning constructors contributed by *David* and *yawned*, is given in (44).

(44)
$$y: \begin{bmatrix} \text{PRED} & \text{'YAWN}\langle\text{SUBJ}\rangle\text{'} \\ \text{SUBJ} & \text{d: } \begin{bmatrix} \text{PRED} & \text{'DAVID'} \end{bmatrix} \end{bmatrix}$$

$$[\text{David}] \qquad David \ : \ d_\sigma$$

$$[\text{yawn}] \qquad \lambda X.yawn(X) \ : \ d_\sigma \multimap y_\sigma$$

The left-hand side of the meaning constructor labeled [**David**] is the proper noun meaning *David*, and the left-hand side of the meaning constructor labeled [**yawn**] is the meaning of the intransitive verb *yawned*, the one-place predicate $\lambda X.yawn(X)$.

We must also provide rules for how the right-hand (glue) side of each of the meaning constructors in (44) relates to the left-hand (meaning) side in a meaning deduction. For simple, nonimplicational meaning constructors such as [**David**] in (44), the meaning on the left-hand side is the meaning of the semantic structure on the right-hand side. For meaning constructors that contain the linear implication operator $\multimap$, such as [**yawn**], *modus ponens* on the glue side corresponds to function application on the meaning side:

(45)
$$\frac{\begin{array}{c} X \ : \ f_\sigma \\ P \ : \ f_\sigma \multimap g_\sigma \end{array}}{P(X) \ : \ g_\sigma}$$

With these correspondences between linear logic formulas and meanings, we perform the following series of reasoning steps:

(46)	*David*: d_σ	The meaning *David* is associated with the SUBJ semantic structure d_σ.
	$\lambda X.yawn(X)$: d_σ—o y_σ	On the glue side, if we find a semantic resource for the SUBJ d_σ, we consume that resource and produce a semantic resource for the full sentence y_σ. On the meaning side, we apply the function $\lambda X.yawn(X)$ to the meaning associated with d_σ.
	yawn (*David*): y_σ	We have produced a semantic structure for the full sentence y_σ, associated with the meaning *yawn*(*David*).

By using the function application rule and the meaning constructors for *David* and *yawned*, we deduce the meaning *yawn* (*David*) for the sentence *David yawned*, as desired.

Glue analyses of quantification, intensional verbs, modification, coordination, and other phenomena have been explored (Dalrymple, 1999). A particular challenge for the glue approach is found in cases in which there are apparently too many or too few meaning resources to produce the correct meaning for a sentence; such cases are explored within the glue framework by Asudeh (2004).

Preferences and Parsing

From its inception, work on LFG has been informed by computational and psycholinguistic concerns. Recent research has combined LFG's syntactic assumptions with an optimality–theoretic approach in an exploration of OT-LFG (*see* **Pragmatics: Optimality Theory; Optimality-Theoretic Lexical-Functional Grammar**). Other work combines LFG with Data-Oriented Parsing, a new view of language processing and acquisition. There have also been significant developments in parsing and generating with LFG grammars and grammars in related formalisms.

Data-Oriented Parsing and Lexical Functional Grammar

The framework of Data-Oriented Parsing (DOP), developed primarily by Rens Bod and his colleagues, represents a new view of the productivity of language and how it can be acquired on the basis of a finite amount of data. DOP views language acquisition as the analysis of a pool of linguistic structures that are presented to the language learner. The learner breaks up these structures into all of their component pieces, from the largest pieces to the smallest units, and new utterances are assembled from these pieces. The likelihood of assigning a particular analysis to a new sentence depends on the frequency of occurrence of its component parts, both large and small, in the original pool of structures.

LFG-DOP (Bod and Kaplan, 1998) specializes the general DOP theory to LFG assumptions about linguistic structures and the relations between them. LFG-DOP assumes that the body of linguistic evidence that a language learner is presented with consists of well-formed c-structure–f-structure pairs. On this view, language acquisition consists in determining the relevant component parts of these structures and then combining these parts to produce new c-structure–f-structure pairs for novel sentences.

Parsing

Several breakthroughs have been made in the parsing of large computational LFG grammars. Maxwell and Kaplan (1991) examined the problem of processing disjunctive specifications of constraints, which are computationally very difficult to process. In the worst case, processing disjunctive constraints is exponentially difficult. However, this worst-case scenario assumes that every disjunctive constraint can interact significantly with every other constraint. In practice, such interactions are found only very rarely. An ambiguity in the syntactic properties of the SUBJ of a sentence rarely correlates with ambiguities in the OBJ or other arguments. This insight is the basis of Maxwell and Kaplan's algorithm, which works by turning a set of disjunctively specified constraints into a set of contexted, conjunctively specified constraints, in which the context of a constraint indicates where the constraint is relevant. Solving these contexted constraints turns out to be very efficient for linguistically motivated sets of constraints, in which only local interactions among disjunctions tend to occur.

Maxwell and Kaplan (1993, 1996) explored the issue of c-structure processing and its relation to

solving f-structural constraints. It has long been known that constituent structure parsing – determining the phrase structure trees for a given sentence – is very fast in comparison to solving the equations that determine the f-structure for the sentence. For this reason, an important task in designing algorithms for linguistic processing of different kinds of structures such as the c-structure and the f-structure is to optimize the interactions between these computationally very different tasks. Previous research often assumed that the most efficient approach would be to interleave the construction of the phrase structure tree with the solution of f-structure constraints. Maxwell and Kaplan (1993) explored and compared a number of different methods for combining phrase structure processing with constraint solving; they showed that in certain situations, interleaving the two processes can actually give very bad results. Subsequently, Maxwell and Kaplan (1996) showed that if phrase structure parsing and f-structural constraint solving are combined in the right way, parsing can be very fast. In fact, if the grammar that results from combining phrase structure and functional constraints happens to be context-free equivalent, the algorithm for computing the c-structure and f-structure operates in cubic time, the same as for pure phrase structure parsing.

Generation

Generation is the inverse of parsing. Whereas the parsing problem is to determine the c-structure and f-structure that correspond to a particular sentence, work on generation in LFG assumes that the generation task is to determine which sentences correspond to a specified f-structure, given a particular grammar. Based on these assumptions, several interesting theoretical results have been attained. Of particular importance is the work of Kaplan and Wedekind (2000), who showed that if we are given an LFG grammar and an *acyclic* f-structure (that is, an f-structure that does not contain a reference to another f-structure that contains it), the set of strings that corresponds to that f-structure according to the grammar is a *context-free language*. Kaplan and Wedekind also provided a method for constructing the context-free grammar for that set of strings by a process of specialization of the full grammar that we are given. This result leads to a new way of thinking about generation; opens the way to new, more efficient generation algorithms; and clarifies a number of formal and mathematical issues relating to LFG parsing and generation.

Wedekind and Kaplan (1996) explored issues in ambiguity-preserving generation, in which a set of f-structures rather than a single f-structure is considered, and the sentences of interest are those that correspond to **all** of the f-structures under consideration. The potential practical advantages of ambiguity-preserving generation are clear. Consider, for example, a scenario involving translation from English to German. We first parse the input English sentence, producing several f-structures if the English sentence is ambiguous. For instance, the English sentence *Hans saw the man with the telescope* is ambiguous: It means either that the man had the telescope or that Hans used the telescope to see the man. The best translation for this sentence would be a German sentence that is ambiguous in exactly the same way as the English sentence, if such a German sentence exists. In the case at hand, we would like to produce the German sentence *Hans sah den Mann mit dem Fernrohr*, which has exactly the same two meanings as the English input. To do this, we map the English f-structures for the input sentence to the set of corresponding German f-structures; our goal is then to generate the German sentence *Hans sah den Mann mit dem Fernrohr*, which corresponds to each of these f-structures. This approach is linguistically appealing, but mathematically potentially problematic. Wedekind and Kaplan (1996) showed that determining whether there is a single sentence that corresponds to each member of a set of f-structures is in general undecidable for an arbitrary (possibly linguistically unreasonable) LFG grammar. This means that there are grammars that can be written within the formal parameters of LFG, even though these grammars may not encode the properties of any actual or potential human language, and, for these grammars, there are sets of f-structures for which it is impossible to determine whether there is any sentence that corresponds to those f-structures. This result is important in understanding the formal limits of ambiguity-preserving generation.

Lexical and Postlexical Phonology

The term 'lexical phonology' is used for two different but related purposes. First, it refers to the range of phonological processes or constraints in a language that pertain to the domain of the word. In this use, it is a synonym of 'word phonology,' and stands in opposition to the term 'postlexical phonology' or 'phrasal phonology.' With the latter term we denote the processes or constraints that apply across the board, not only within the domain of the word, but also across word boundaries in the domain of larger constituents such as phrases. The distinction between these two domains of phonology can be illustrated by means of the following example. In Dutch, obstruents

(stops and fricatives) are always voiceless at the end of a syllable (a generalization referred to as final devoicing). This constraint is part of word phonology, as illustrated by the following minimal pair:

vind-er [vɪn.dər] 'finder'
vind er [vɪn.tər] 'find her'

The first example is a noun ending in the suffix *-er* derived from the verb *vind* 'to find'. Final devoicing is not applicable here since the stem-final /d/ is syllabified as an onset (syllable boundaries in phonetic forms are indicated by dots). In the second example the clitic pronoun *er* /ər/ 'her' forms one prosodic word with the preceding verb. However, the /d/ is realized as [t], showing that it must have been in coda position at the presyntactic level, before this word was combined with the clitic pronoun. This shows that final devoicing is a constraint that is part of the word phonology of Dutch, whereas the syllabification of the verb and the following clitic as one prosodic word belongs to the domain of phrasal (postlexical) phonology. As this example illustrates, rules of word phonology must apply before phrasal phonology. Another example of this distinction is that Dutch simplex and derived words do not have geminate consonants. The past tense form *eette* /e:t-tə/ of the verb *eet* 'to eat', with the past tense suffix *-te*, for instance, is realized as [e:tə]. Hence, there is an obligatory rule of degemination as part of the word phonology of Dutch. Across word boundaries, however, geminate consonants do occur, but they may be reduced to one consonant in casual or fast speech. Thus, the same process may function as an obligatory rule at the level of word phonology, and as an optional rule in phrasal phonology.

The term 'lexical phonology' is also used to denote a particular theory about the interaction between morphology and phonology, in which the distinction between word phonology and phrasal phonology discussed above plays an important role. This theory will be discussed in the next section.

Lexical Phonology and Morphology

Lexical phonology is a theory about the interface between phonology and morphology developed by Paul Kiparsky (1982, 1985) and a number of other phonologists. The basic issue is to what extent and how the morphological structure of words determines their phonetic realization. Lexical phonology may be qualified as a set of related but independent hypotheses about the morphology–phonology interface (see Booij, 2000 for a detailed survey).

The basic claim of lexical phonology is that morphology and the rules of word phonology apply in tandem. Given a word with its underlying phonological form, the relevant rules of word phonology are applied to that word. You may then apply a morphological rule to that word in its derived phonological form. This creates a new domain of application for the rules of word phonology. Thus, we derive the lexical phonetic forms of words. These words will subsequently be combined into phrases and larger constituents by the rules of syntax. Postlexical phonology is accounted for by a component of postlexical phonology that applies after syntax. Thus, the organization of the grammar is proposed as in Figure 1.

Suppose we want to compute the phonetic form of the 1.sg. form of the Dutch verb *vind* /vɪnd/ 'to find', which is *vind* [vɪnt]. The stem for *vind* is first fed into morphology, which has no phonological effect since there is no overt morphological ending for 1.sg. verbs. The form is then syllabified, as one syllable (vɪnd). To this form, the rule of final devoicing applies, resulting in the form [vɪnt]. This is the form that is fed into syntax. At the postlexical level, this form may undergo further phonological rules such as assimilation.

We do not have to label the rule of final devoicing explicitly as a lexical rule. Instead, we might assume the principle 'apply a rule when possible.' Thus, the rules of syllabification will apply to a word. Subsequently, the presence of syllable structure will trigger application of the rule of final devoicing to voiced obstruents in syllable-final position.

When we derive the deverbal noun *vinder* with the phonetic form [vɪn.dər] we might proceed as

Figure 1 Lexical phonology.

follows. On the assumption that stems do not trigger the application of phonological rules, the stem *vind* is fed into morphology, where the noun *vinder* is created. Subsequently, this word will be syllabified as *vin.der*. The /d/ is now in onset position and hence it will not be devoiced, as required. This word is then, with this computed phonological form, available for lexical insertion into syntactic structure.

The theory of lexical phonology in its original form claimed that word phonological rules may apply cyclically, in an outward fashion. The concept of cyclic rule application originates from Chomsky and Halle (1968) (usually referred to as *SPE*), which proposed to apply the stress rules of English in a cyclic fashion. For example, the stress patterns of the word *condensation* in the (deverbal) interpretation 'the act of condensing' and of the similar word *compensation* are derived in two steps. On the first cycle, main stress is assigned to their verbal stems *con**dense*** and ***com**pensate* respectively, which results in main stress on the second and first syllable respectively. The addition of the suffix *-ation* creates a second domain of application of the English main stress rule, with main stress on the first vowel of *-ation*. There is also some degree of stress on the word-initial syllables of these words. These words differ, however, in the phonetic realization of the second vowel. The second, unstressed vowel of *compensation*, which is unstressed on both cycles, is realized as a schwa, whereas the second vowel of *condensation* is pronounced as a full vowel [ɛ] since it still has some degree of stress, a reflex of the stress pattern of its verbal stem *condense*. The difference in phonetic realization of the second vowel of these words thus reflects their derivational history (Chomsky and Halle, 1968: 116).

Whereas in *SPE* cyclic application of the English stress rules is stipulated, in lexical phonology this manner of application follows from the organization of the grammar as outlined above, since the derived phonological forms of words can be fed back into the morphological component. Therefore, it has been proposed that the rules of lexical phonology apply as soon as possible, hence cyclically. An additional advantage of this theory is that it predicts that morphological operations can be dependent on derived phonological properties of words. An example of this kind of dependence is that the English suffix *-al* can only be attached to verbs that bear main stress on their final syllable; hence the difference between *try–trial* versus *organize–*organizal* (the only exception to this constraint is *bury–burial*). If stress can be computed by rule in a cyclic fashion, the grammar will first assign stress to the verbal stems, and subsequently, the word formation rule for *-al* can be applied to verbal stems provided with the required stress pattern.

This proposal raises a number of issues. First, stress is a property of syllables. Hence, if stress is cyclic, syllabification must be applied in a cyclic fashion as well. Affixation may, however, affect the syllabification of the stem. In particular, stem-final consonants will be syllabified as codas, but syllabified as onsets when a vowel-initial suffix is attached to that stem, as in *find–fin.der*. Cyclic syllabification thus implies some form of resyllabification of the stem on the next cycle. Secondly, it has become clear that certain phonological rules should not apply cyclically. This is, for example, the case for the Dutch rule of final devoicing, which should not apply to the stem of the deverbal noun *vind-er* discussed above because otherwise the wrong phonetic form [vɪn.tər] is predicted. Therefore, Booij and Rubach (1987) proposed a refinement of the model of lexical phonology, and introduced a third level, a category of presyntactic word-level rules (also called postcyclic rules) that apply after the set of cyclic phonological rules, but still within the lexicon. Hence, we get three levels of application of phonological rules:

1. Cyclic phonological rules (interacting with word formation)
2. Word-level phonological rules
3. Postlexical phonological rules.

A related hypothesis is that cyclic rules are subject to the condition that they apply in derived environments only. This means that they can only apply in a context created by the application of a previous phonological or morphological operation (see Booij, 2000 for detailed discussion). Furthermore, it has been hypothesized that lexical rules are structure preserving; that is, they only introduce phonological segments that also occur in the underlying forms of words.

In some varieties of lexical phonology one also finds the hypothesis of level ordering. This hypothesis claims that the morphological processes of a language may be organized in two or more levels or strata, each with their own set of phonological rules applying to the complex words created at that level. For English, for instance, it has been proposed that there are two levels. Level 1 is the level of nonnative suffixation, which triggers the application of a specific set of phonological rules such as the main stress rule. Level 2 is the level for stress-neutral (native derivational and inflectional) suffixes. At this level, the main stress rule no longer applies, thus accounting for the stress-neutrality of these suffixes. This level-ordering

hypothesis also predicts that stress-neutral suffixes are peripheral to those that influence the stress patterns of words, such as the stress-bearing nonnative (Romance) suffixes of English. For instance, in the complex noun *contrastiveness* the stress-shifting suffix *-ive* precedes the stress-neutral suffix *-ness*. The level-ordering hypothesis for English is discussed and criticized in detail by Fabb (1988) and Plag (1999), and defended in Giegerich (1999).

Constraint-Based Phonology

To what extent do the insights of lexical phonology carry over to constraint-based phonological theories such as optimality theory (OT)? An important insight of lexical phonology is that morphological structure may determine the domain of application of phonological constraints. This insight has been carried over to OT in the subtheory of alignment (McCarthy and Prince, 1994). In this approach, the boundaries of prosodic constituents such as syllables and prosodic words must be aligned as much as possible with morphological boundaries. Thus, morphological boundaries codetermine the boundaries of prosodic constituents, and hence indirectly the domain of application of phonological rules. The effects of cyclic application of phonological rules within complex words in rule-based frameworks might be obtained by making use of output–output identity constraints that refer to the phonetic form of morphologically related words or word forms (Benua, 2000).

The distinction between word phonology and phrase phonology can be carried over to OT in the form of derivational optimality theory (DOT), as advocated in Booij (1997), Rubach (2000), and Ito and Mester (2001). This means that the evaluation of the candidate phonetic forms of words takes place in two steps, first at the word level, and subsequently at the postlexical level. Thus a restricted form of derivation is maintained. This approach can account for the difference in phonetic form between *vinder* and *vind er* mentioned above.

Lexical Semantics: Overview

Word Knowledge

Semantic interpretation requires access to knowledge about words. The lexicon of a grammar must provide a systematic and efficient way of encoding the information associated with words in a language. Lexical semantics is the study of what words mean and how they structure these meanings. This article examines word meaning from two different perspectives: the information required for composition in the syntax and the knowledge needed for semantic interpretation. The lexicon is not merely a collection of words with their associated phonetic, orthographic, and semantic forms. Rather, lexical entries are structured objects that participate in larger operations and compositions, both enabling syntactic environments and acting as signatures to semantic entailments and implicatures in the context of larger discourse.

There are four basic questions in modeling the semantic content and structure of the lexicon: (1) What semantic information goes into a lexical entry? (2) How do lexical entries relate semantically to one another? (3) How is this information exploited compositionally by the grammar? and (4) How is this information available to semantic interpretation generally? This article focuses on the first two.

The lexicon and lexical semantics have traditionally been viewed as the most passive modules of language, acting in the service of the more dynamic components of the grammar. This view has its origins in the generative tradition (Chomsky, 1955) and has been an integral part of the notion of the lexicon ever since. While the *aspects* model of selectional features (Chomsky, 1965) restricted the relation of selection to that between lexical items, work by McCawley (1968) and Jackendoff (1972) showed that selectional restrictions must be available to computations at the level of derived semantic representation rather than at deep structure. Subsequent work by Bresnan (1982), Gazdar *et al*. (1985), and Pollard and Sag (1994) extended the range of phenomena that can be handled by the projection and exploitation of lexically derived information in the grammar.

With the convergence of several areas in linguistics (lexical semantics, computational lexicons, and type theories) several models for the determination of selection have emerged that put even more compostional power in the lexicon, making explicit reference to the paradigmatic systems that allow for grammatical constructions to be partially determined by selection. Examples of this approach are generative lexicon theory (Bouillon and Busa, 2001; Pustejovsky, 1995) and construction grammar (Goldberg, 1995; Jackendoff, 1997, 2002). These developments have helped to characterize the approaches to lexical design in terms of a hierarchy of semantic expressiveness. There are at least three such classes of lexical description: *sense enumerative lexicons*, where lexical items have a single type and meaning, and ambiguity is treated by multiple listings of words; *polymorphic lexicons*, where lexical items are active objects, contributing to the determination of meaning in context, under well-defined constraints; and *unrestricted sense lexicons*, where the meanings of lexical items are determined mostly by context and conventional use. Clearly, the most promising direction seems to be a careful and formal elucidation of the *polymorphic lexicons*, and this will form the basis of the subsequent discussion of both the structure and the content of lexical entries.

Historical Overview

The study of word meaning has occupied philosophers for centuries, beginning at least with Aristotle's theory of meaning. Locke, Hume, and Reid all paid particular attention to the meanings of words, but not until the 19th century did the rise of philological and psychological investigations of word meaning occur, with Bréal (1897), Erdmann (1900), Trier (1931), Stern (1931/1968), and others focused on word connotation, semantic drift, and word associations in the mental lexicon as well as in social contexts.

Interestingly, Russell, Frege, and other early analytic philosophers were not interested in language as a linguistic phenomenon but simply as the medium through which judgments can be formed and expressed. Hence, there is little regard for the relations between senses of words, when not affecting the nature of judgment, for example, within intensional contexts. Nineteenth-century semanticists and semasiologists, on the other hand, viewed polysemy as the life force of human language. Bréal, for example, considered it to be a necessary creative component of language and argued that this phenomenon better than most in semantics illustrates the cognitive and conceptualizing force of the human species.

Even with their obvious enthusiasm, semasiology produced no lasting legacy to the study of lexical semantics. In fact, there was no systematic research into lexical meaning until structural linguists extended the relational techniques of Saussure (1916/1983) and elaborated the framework of componential analysis for language meaning (Jakobson, 1970).

The idea behind componential analysis is the reduction of a word's meaning into its ultimate contrastive elements. These contrastive elements are structured in a matrix, allowing for dimensional analysis and generalizations to be made about lexical sets occupying the cells in the matrix.

This technique developed into a general framework for linguistic description called distinctive feature analysis (Jakobson and Halle, 1956). This is essentially the inspiration for Katz and Fodor's 1963 theory of lexical semantics within transformational grammar. In this theory, usually referred to as 'markerese,' a lexical entry in the language consists of grammatical and semantic markers and a special feature called a '*semantic distinguisher*.' In Weinreich (1972) and much subsequent discussion, it was demonstrated that this model is far too impoverished to characterize the compositional mechanisms inherent in language. In the late 1960s and early 1970s, alternative models of word meaning emerged (Fillmore, 1965; Gruber, 1965; Jackendoff, 1972; Lakoff, 1965) that respected the relational structure of sentence meaning while encoding the named semantic functions in lexical entries. In Dowty (1979), a model theoretic interpretation of the decompositional techniques of Lakoff, McCawley, and Ross was developed.

Recently, the role of lexical–syntactic mapping has become more evident, particularly with the growing concern over projection from lexical semantic form, the problem of verbal alternations and polyvalency, and the phenomenon of polysemy.

Ambiguity and Polysemy

Given the compactness of a lexicon relative to the number of objects and relations in the world, and the concepts we have for them, lexical ambiguity is inevitable. Add to this the cultural, historical, and linguistic blending that contributes to the meanings of our lexical items, and ambiguity can appear arbitrary as well. Hence, '*homonymy*' – where one lexical form has many meanings – is to be expected in a language. Examples of homonyms are illustrated in the following sentences:

(1a) Mary walked along the bank of the river.
(1b) Bank of America is the largest bank in the city.

(2a) Drop me a line when you are in Boston.
(2b) We built a fence along the property line.

(3a) First we leave the gate, then we taxi down the runway.
(3b) John saw the taxi on the street.

(4a) The judge asked the defendant to approach the bar.
(4b) The defendant was in the pub at the bar.

Weinreich (1964) calls such lexical distinctions '*contrastive ambiguity*,' where it is clear that the senses associated with the lexical item are unrelated. For this reason, it is generally assumed that homonyms are represented as separate lexical entries within the organization of the lexicon. This accords with a view of lexical organization that has been termed a '*sense enumeration lexicon*' (cf. Pustejovsky, 1995). That is, a lexicon is *sense enumerative* when every word ω that has multiple senses stores these senses as separate lexical entries.

This model becomes difficult to maintain, however, when we consider the phenomenon known as '*polysemy*.' Polysemy is the relationship that exists between different senses of a word that are related in some logical manner rather than arbitrarily, as in the previous examples. We can distinguish three broad types of polysemy, each presenting a novel set of challenges to lexical semantics and linguistic theory.

a. Deep semantic typing: single argument polymorphism
b. Syntactic alternations: multiple argument polymorphism
c. Dot objects: lexical reference to objects that have multiple facets

The first class refers mainly to functors allowing a range of syntactic variation in a single argument. For example, aspectual verbs (*begin* and *finish*), perception verbs (*see, hear*), and most propositional attitude verbs (*know, believe*) subcategorize for multiple syntactic forms in complement position, as illustrated in (6):

(5a) Mary began to read the novel.
(5b) Mary began reading the novel.
(5c) Mary began the novel.

(6a) Bill saw John leave.
(6b) Bill saw John leaving.
(6c) Bill saw John.

(7a) Mary believes that John told the truth.
(7b) Mary believes what John said.
(7c) Mary believes John's story.

What these and many other cases of multiple selection share is that the underlying relation between the verb and each of its complements is essentially identical. For example, in (7), the complement to the verb *believe* in all three sentences is a proposition; in (5), what is begun in each sentence is an event of some sort; and in (6), the object of the perception is (arguably) an event in each case. This has led some linguists to argue for semantic selection (cf. Chomsky, 1986; Grimshaw, 1979) and others to argue for structured

selectional inheritance (Godard and Jayez, 1993). In fact, these perspectives are not that distant from one another (cf. Pustejovsky, 1995): in either view, there is an explicit lexical association between syntactic forms that is formally modeled by the grammar.

The second type of polysemy (syntactic alternations) involves verbal forms taking arguments in alternating constructions, the so-called '*verbal alternations*' (cf. Levin, 1993). These are true instances of polysemy because there is a logical (typically *causal*) relation between the two senses of the verb. As a result, the lexicon must either relate the senses through lexical rules (such as in head-driven phrase structure grammar (HPSG) treatments; cf. Pollard and Sag, 1994) or assume that there is one lexical form that has multiple syntactic realizations (cf. Pustejovsky and Busa, 1995).

(8a) The window opened suddenly.
(8b) Mary opened the window suddenly.

(9a) Bill began his lecture on time.
(9b) The lecture began on time.

(10a) The milk spilled onto the table.
(10b) Mary spilled the milk onto the table.

The final form of polysemy reviewed here is encountered mostly in nominals and has been termed '*regular polysemy*' (cf. Apresjan, 1973) and '*logical polysemy*' (cf. Pustejovsky, 1991) in the literature; it is illustrated in the following sentences:

(11a) Mary carried the book home.
(11b) Mary doesn't agree with the book.

(12a) Mary has her lunch in her backpack.
(12b) Lunch was longer today than it was yesterday.

(13a) The flight lasted 3 hours.
(13b) The flight landed on time in Los Angeles.

Notice that in each of the pairs, the same nominal form is assuming different semantic interpretations relative to its selective context. For example, in (11a) the noun *book* refers to a physical object, whereas in (11b) it refers to the informational content. In (12a), *lunch* refers to the physical manifestation of the food, whereas in (12b) it refers to the eating event. Finally, in (13a) *flight* refers to the flying event, whereas in (13b) it refers to the plane. This phenomenon of polysemy is one of the most challenging in the area and has stimulated much research Bouillon, 1997; Bouillon and Busa, 2001. In order to understand how each of these cases of polysemy can be handled, we must first familiarize ourselves with the structure of individual lexical entries.

Lexical Relations

Another important aspect of lexical semantics is the study of how words are semantically related to one another. Four classes of lexical relations, in particular, are important to recognize: synonymy, antonymy, hyponymy, and meronymy.

Synonymy is generally taken to be a relation between words rather than concepts. One fairly standard definition states that two expressions are synonymous if substituting one for the other in all contexts does not change the truth value of the sentence where the substitution is made (cf. Cruse, 1986, 2004; Lyons, 1977). A somewhat weaker definition makes reference to the substitution relative to a specific context. For example, in the context of carpentry, *plank* and *board* might be considered synonyms, but not necessarily in other domains (cf. Miller *et al.*, 1990). The relation of antonymy is characterized in terms of semantic opposition and, like synonymy, is properly defined over pairs of lexical items rather than concepts. Examples of antonymy are *rise/fall*, *heavy/light*, *fast/slow*, and *long/short* (cf. Cruse, 1986; Miller, 1991). It is interesting to observe that co-occurrence data illustrate that synonyms do not necessarily share the same antonyms. For example, *rise* and *ascend* as well as *fall* and *descend* are similar in meaning, yet neither *fall/ascend* nor *rise/descend* are antonym pairs. For further details see Miller *et al.* (1990).

The most studied relation in the lexical semantic community is hyponymy, the taxonomic relationship between words, as defined in WordNet (Fellbaum, 1998) and other semantic networks. For example, specifying *car* as a hyponym of *vehicle* is equivalent to saying that *vehicle* is a superconcept of the concept *car* or that the set *car* is a subset of those individuals denoted by the set *vehicle*.

One of the most difficult lexical relations to define and treat formally is that of meronymy, the relation of parts to the whole. The relation is familiar from knowledge representation languages with predicates or slot-names such as 'part-of' and 'made-of.' For treatments of this relation in lexical semantics, see Miller *et al.* (1990) and Cruse (1986).

The Semantics of a Lexical Entry

It is generally assumed that there are four components to a lexical item: phonological, orthographic, syntactic, and semantic information. Here, we focus first on syntactic features and then on what semantic information must be encoded in an individual lexical entry.

There are two types of syntactic knowledge associated with a lexical item: its *category* and its *subcategory*. The former includes traditional classifications of both the major categories, such as noun, verb, adjective, adverb, and preposition, as well as the minor categories, such as adverbs, conjunctions, quantifier elements, and determiners. Knowledge of the subcategory of a lexical item is typically information that differentiates categories into distinct, distributional classes. This sort of information may be usefully separated into two types, *contextual features* and *inherent features*. The former are features that may be defined in terms of the contexts in which a given lexical entry may occur. Subcategorization information marks the local syntactic context for a word. It is this information that ensures that the verb *devour*, for example, is always transitive in English, requiring a direct object; the lexical entry encodes this requirement with a subcategorization feature specifying that a noun phrase (NP) appear to its right. Another type of context encoding is collocational information, where patterns that are not fully productive in the grammar can be tagged. For example, the adjective *heavy* as applied to *drinker* and *smoker* is collocational and not freely productive in the language (Mel'čuk, 1988). '*Inherent features*' on the other hand, are properties of lexical entries that are not easily reduced to a contextual definition but, rather, refer to the ontological typing of an entity. These include such features as count/mass (e.g., *pebble* vs. *water*), abstract, animate, human, physical, and so on.

Lexical items can be systematically grouped according to their syntactic and semantic behavior in the language. For this reason, there have been two major traditions of word clustering, corresponding to this distinction. Broadly speaking, for those concerned mainly with grammatical behavior, the most salient aspect of a lexical item is its *argument structure*; for those focusing on a word's entailment properties, the most important aspect is its *semantic class*. In this section, these two approaches are examined and it is shown how their concerns can be integrated into a common lexical representation.

Lexical Semantic Classifications

Conventional approaches to lexicon design and lexicography have been relatively informal with regard to forming taxonomic structures for the word senses in the language. For example, the top concepts in WordNet (Miller *et al.*, 1990) illustrate how words are characterized by local clusterings of semantic properties. As with many ontologies, however, it is difficult to discern a coherent global structure for the resulting classification beyond a weak descriptive labeling of words into extensionally defined sets.

Figure 1 Type structures.

One of the most common ways to organize lexical knowledge is by means of type or feature inheritance mechanisms (Carpenter, 1992; Copestake and Briscoe, 1992; Evans and Gazdar, 1990; Pollard and Sag, 1994). Furthermore, Briscoe *et al.* (1993) described a rich system of types for allowing default mechanisms into lexical type descriptions. Similarly, type structures, such as that shown in Figure 1, can express the inheritance of syntactic and semantic features, as well as the relationship between syntactic classes and alternations (cf. Alsina, 1992; Davis, 1996; Koenig and Davis, 1999; Sanfilippo, 1993) and other relations (cf. Pustejovsky, 2001; Pustejovsky and Boguraev, 1993).

In the remainder of this section, we first examine the approach to characterizing the weak constraints imposed on a lexical item associated with its arguments. Then, we examine attempts to model lexical behavior by means of internal constraints imposed on the predicate. Finally, it is shown how, in some respects, these are very similar enterprises and both sets of constraints may be necessary to model lexical behavior.

Argument Structure

Once the base syntactic and semantic typing for a lexical item has been specified, its subcategorization and selectional information must be encoded in some form. There are two major techniques for representing this type of knowledge:

1. Associate 'named roles' with the arguments to the lexical item (Fillmore, 1985; Gruber, 1965; Jackendoff, 1972).
2. Associate a logical decomposition with the lexical item; meanings of arguments are determined by how the structural properties of the representation are interpreted (cf. Hale and Keyser, 1993; Jackendoff, 1983; Levin and Rappaport, 1995).

One influential way of encoding selectional behavior has been the theory of *thematic relations* (cf. Gruber, 1976; Jackendoff, 1972). Thematic relations are now generally defined as partial semantic functions of the event being denoted by the verb or noun, and they behave according to a predefined calculus of roles relations (e.g., Dowty, 1989). For example, semantic roles such as agent, theme, and goal can be used to partially determine the meaning of a predicate when they are associated with the grammatical arguments to a verb.

(14a) **put** <AGENT, THEME, LOCATION>
(14b) **borrow** <RECIPIENT, THEME, SOURCE>

Thematic roles can be ordered relative to each other in terms of an implicational hierarchy. For example, there is considerable use of a universal subject hierarchy such as is shown in the following (cf. Comrie, 1981; Fillmore, 1968):

(15) AGENT > RECIPIENT/BENEFACTIVE > THEME/PATIENT > INSTRUMENT > LOCATION>

Many linguists have questioned the general explanatory coverage of thematic roles, however, and have have chosen alternative methods for capturing the generalizations they promised. Dowty (1991) suggested that theta-role generalizations are best captured by entailments associated with the predicate. A theta-role can then be seen as the set of predicate entailments that are properties of a particular argument to the verb. Characteristic entailments might be thought of as prototype roles, or proto-roles; this allows for degrees or shades of meaning associated with the arguments to a predicate. Others have opted for a more semantically neutral set of labels to assign to the parameters of a relation, whether it is realized as a verb, noun, or adjective. For example, the theory of argument structure as developed by Williams (1981), Grimshaw (1990), and others can be seen as a move toward a more minimalist description of semantic differentiation in the verb's list of parameters. The argument structure for a word can be seen as the simplest specification of its semantics, indicating the number and type of parameters associated with the lexical item as a predicate. For example, the verb *die* can be represented as a predicate taking one argument, *kill* as taking two arguments, where as the verb *give* takes three arguments:

(16a) **die** (x)
(16b) **kill** (x,y)
(16c) **give** (x,y,z)

What originally began as the simple listing of the parameters or arguments associated with a predicate has developed into a sophisticated view of the way arguments are mapped onto syntactic expressions. Williams's (1981) distinction between *external* (the underlined arguments above) and *internal* arguments and Grimshaw's proposal for a hierarchically structured representation (cf. Grimshaw, 1990) provide us with the basic syntax for one aspect of a word's meaning. Similar remarks hold for the argument list structure in HPSG (Pollard and Sag, 1994) and Lexical Functional Grammar (Bresnan, 1994).

The interaction of a structured argument list and a rich system of types, such as that presented previously, provides a mechanism for semantic selection through inheritance. Consider, for instance, the sentence pairs in (17):

(17a) The man/the rock fell.
(17b) The man/*the rock died.

Now consider how the selectional distinction for a feature such as animacy is modeled so as to explain the selectional constraints of predicates. For the purpose of illustration, the arguments of a verb will be identified as being typed from the system shown previously.

(18a) λx: physical[**fall**($\underline{x}$)]
(18b) λx: animate[**die**($\underline{x}$)]

In the sentences in (17), it is clear how rocks cannot die and men can, but it is still not obvious how this judgment is computed, given what we would assume are the types associated with the nouns *rock* and *man*, respectively. What accomplishes this computation is a rule of subtyping, Θ, that allows the type associated with the noun *man* (i.e., 'human') to also be accepted as the type 'animate,' which is what the predicate *die* requires of its argument as stated in (18b) (cf. Carpenter, 1992).

(19) Θ [*human* $\sqsubseteq$ *animate*]: *human* $\rightarrow$ *animate*

The rule Θ, applies since the concept 'human' is subtyped under 'animate' in the type hierarchy. Parallel considerations rule out the noun *rock* as a legitimate argument to *die* since it is not subtyped under 'animate.' Hence, one of the concerns given previously for how syntactic processes can systematically keep track of which 'selectional features' are entailed and which are not is partially addressed by such lattice traversal rules as the one presented here.

Event Structure and Lexical Decomposition

The second approach to lexical specification mentioned previously is to define constraints internally to the predicate. Traditionally, this has been known as 'lexical decomposition.' In this section, we review

the motivations for decomposition in linguistic theory and the proposals for encoding lexical knowledge as structured objects. We then relate this to the way in which verbs can be decomposed in terms of eventualities (Tenny and Pustejovsky, 2000).

Since the 1960s, lexical semanticists have attempted to formally model the semantic relations between lexical items such as between the adjective *dead* and the verbs *die* and *kill* (cf. Lakoff, 1965; McCawley, 1968) in the following sentences:

(20a) John killed Bill.
(20b) Bill died.
(20c) Bill is dead.

Assuming the underlying form for a verb such as *kill* directly encodes the stative predicate in (20c) and the relation of causation, generative semanticists posited representations such as (21):

(21) (CAUSE (x, (BECOME (NOT (ALIVE y))))

Here the predicate CAUSE is represented as a relation between an individual causer *x* and an expression involving a change of state in the argument *y*. Carter (1976) proposes a representation quite similar, shown here for the causative verb *darken*:

(22) (x CAUSE ((y BE DARK) CHANGE))

Although there is an intuition that the cause relation involves a causer and an event, neither Lakoff nor Carter make this commitment explicitly. In fact, it has taken several decades for Davidson's (1967) observations regarding the role of events in the determination of verb meaning to find their way convincingly into the major linguistic frameworks. A new synthesis has emerged that attempts to model verb meanings as complex predicative structures with rich event structures (cf. Hale and Keyser, 1993; Parsons, 1990; Pustejovsky, 1991). This research has developed the idea that the meaning of a verb can be analyzed into a structured representation of the event that the verb designates, and it has furthermore contributed to the realization that verbs may have complex, internal event structures. Recent work has converged on the view that complex events are structured into an inner and an outer event, where the outer event is associated with causation and agency, and the inner event is associated with telicity (completion) and change of state (cf. Tenny and Pustejovsky, 2000).

Jackendoff (1990) developed an extensive system of what he calls '*conceptual representations*,' which parallel the syntactic representations of sentences of natural language. These employ a set of canonical predicates, including CAUSE, GO, TO, and ON, and canonical elements, including Thing, Path, and Event. These approaches represent verb meaning by decomposing the predicate into more basic predicates. This work owes obvious debt to the innovative work within generative semantics, as illustrated by McCawley's (1968) analysis of the verb *kill*. Recent versions of lexical representations inspired by generative semantics can be seen in the lexical relational structures of Hale and Keyser (1993), where syntactic tree structures are employed to capture the same elements of causation and change of state as in the representations of Carter, Levin and Rapoport, Jackendoff, and Dowty. The work of Levin and Rappaport, building on Jackendoff's lexical conceptual structures, has been influential in further articulating the internal structure of verb meanings (Levin and Rappaport, 1995).

Pustejovsky (1991) extended the decompositional approach presented in Dowty (1979) by explicitly reifying the events and subevents in the predicative expressions. Unlike Dowty's treatment of lexical semantics, where the decompositional calculus builds on propositional or predicative units (as discussed previously) a 'syntax of event structure' makes explicit reference to quantified events as part of the word meaning. Pustejovsky further introduced a tree structure to represent the temporal ordering and dominance constraints on an event and its subevents. For example, a predicate such as *build* is associated with a complex event such as the following (cf. also Moens and Steedman, 1988):

(23) $[_{transition}[e_1\text{:PROCESS}]\ [e_2\text{:STATE}]]$

The process consists of the building activity itself, whereas the state represents the result of there being the object built. Grimshaw (1990) adopted this theory in her work on argument structure, where complex events such as *break* are given a similar representation. In such structures, the process consists of what *x* does to cause the breaking, and the state is the resultant state of the broken item. The process corresponds to the outer causing event as discussed previously, and the state corresponds in part to the inner change of state event. Both Pustejovsky and Grimshaw differ from the previous authors in assuming a specific level of representation for event structure, distinct from the representation of other lexical properties. Furthermore, they follow Higginbotham (1985) in adopting an explicit reference to the event place in the verbal semantics.

Rappaport and Levin (2001) adopted a large component of the event structure model for their analysis of the resultative construction in English. Event decomposition has also been employed for properties of adjectival selection, the interpretation of compounds, and stage and individual-level predication.

Qualia Structure

Thus far, we have focused on the lexical semantics of verb entries. All of the major categories, however, are encoded with syntactic and semantic feature structures that determine their constructional behavior and subsequent meaning at logical form. In generative lexicon theory (Pustejovsky, 1995), it is assumed that word meaning is structured on the basis of four generative factors, or '*qualia roles*', that capture how humans understand objects and relations in the world and provide the minimal explanation for the linguistic behavior of lexical items (these are inspired in large part by Moravcsik's (1975, 1990) interpretation of Aristotelian *aitia*). These are the formal role, the basic category that distinguishes the object within a larger domain; the constitutive role, the relation between an object and its constituent parts; the telic role, its purpose and function; and the agentive role, factors involved in the object's origin or 'coming into being.' Qualia structure is at the core of the generative properties of the lexicon since it provides a general strategy for creating new types. For example, consider the properties of nouns such as *rock* and *chair*. These nouns can be distinguished on the basis of semantic criteria that classify them in terms of general categories such as *natural_kind, artifact_object*. Although very useful, this is not sufficient to discriminate semantic types in a way that also accounts for their grammatical behavior. A crucial distinction between *rock* and *chair* concerns the properties that differentiate *natural_kinds* from *artifacts*: Functionality plays a crucial role in the process of individuation of artifacts but not of natural kinds. This is reflected in grammatical behavior, whereby 'a good chair' or 'enjoy the chair' are well-formed expressions reflecting the specific purpose for which an artifact is designed, but 'good rock' or 'enjoy a rock' are semantically ill formed since for *rock* the functionality (i.e., telic) is undefined. Exceptions exist when new concepts are referred to, such as when the object is construed relative to a specific activity, as in 'The climber enjoyed that rock'; *rock* takes on a new meaning by virtue of having telicity associated with it, and this is accomplished by integration with the semantics of the subject NP. Although *chair* and *rock* are both *physical_object*, they differ in their mode of coming into being (i.e., agentive): artifacts are man-made, *rocks* develop in nature. Similarly, a concept such as *food* or *cookie* has a physical manifestation or denotation, but also a functional grounding, pertaining to the relation of 'eating.' These apparently contradictory aspects of a category are orthogonally represented by the qualia structure for that concept, which provides a coherent structuring for different dimensions of meaning.

Lexicalization

K Bakken, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Lexicalization – A Variable Concept

The term lexicalization is used with a broad range of related but distinct meanings within linguistics. One very basic meaning of the word pertains specifically to conceptualization. Concepts, which are expressed by a lexical form, may be described as 'lexicalized.' A lexicalized concept could be juxtaposed to a concept that is not lexicalized, for example, in a comparison of languages (cf. Lyons, 1977: 235; Talmy, 1985). The concept 'the succession of one day and one night' is thus lexicalized as *døgn* in Norwegian (and Danish), but has no lexical equivalent in English.

New concepts that are given lexical form become part of the lexicon of a language and the process of establishing a new unit in any specific lexicon is commonly referred to as lexicalization. All new words and meanings may thus potentially be lexicalized and the term is often activated in discussions of the integration of loan words, the development of new meanings, and the establishing of idioms as lexical units. Most important in this respect is the concept's relevance to regular word-formation processes, which is discussed below.

Another use of lexicalization indicates a contrast to grammaticalization. Lehmann (1989) compares the two concepts by defining them as processes that move signs in different directions across the border between lexicon and grammar. Moreno Cabrera (1998), on the other hand, defines the relationship between the phenomena as complementary; grammaticalization involves metaphorical abstraction processes, whereas lexicalization has to do with metonymical concretion. Grammaticalization viewed in this light represents a well-developed field of linguistic research, whereas lexicalization thus conceived does not. Hopper and Traugott (1993: 49) briefly refer to lexicalization as the rare "process whereby a nonlexical form such as *up* becomes a fully referential lexical item," thus evoking the difference between grammatical and lexical words.

Finally, a fairly common use of lexicalization refers to the process when morphosyntactic, syntactic, or pragmatic means of conveying information are taken over by lexical forms. One example is Moore (1988), who demonstrates how productive morphosyntactic categories are lexicalized word by word in a situation of language obsolescence; another is Bybee (1985: 18), who refers to examples where once productive causatives or present-tense morphemes are reanalyzed as lexical forms.

Lexicalization and the Lexicon

In broad terms, lexicalization has to do with including new items in the lexicon. Therefore, one's conceptualization of the lexicon is a prerequisite for the use one makes of the term lexicalization. Pawley (1986) makes a point of contrasting the then-dominant structuralist or generative notion of the lexicon with that implied by lexicographers and 'lay lexicographers.'

Since 1986, linguistics has undergone a major shift in the relative amount of interest paid to the lexicon. The 'lexicographers' lexicon' that Pawley pointed to can much more easily be harmonized with the new host of usage-based theories, with cognitive linguistics being the most elaborated framework (cf. Langacker, 1987, 1991, 2000). Here, the mental lexicon is seen as the primary locus of the human language capacity, the network is a metaphor much used to describe its organization, and the distinction between productive rules and stored units is to a large degree erased.

Lexicalization is thus dependent on theories of the lexicon. Lexicalization used within generative theories such as the Lexicalist approach during the 1970s (cf. Bauer, 1988) or within Lexical Morphology during the 1980s evokes a host of theoretical assumptions that cannot easily be compared to those evoked by linguists working within usage-based theories (cf., for example, Svanlund, 2002).

Lexicalization and Word Formation

It is only in relation to regular word formation that lexicalization has been the focus of major research on

Lexicalization – A Variable Concept

The term lexicalization is used with a broad range of related but distinct meanings within linguistics. One very basic meaning of the word pertains specifically to conceptualization. Concepts, which are expressed by a lexical form, may be described as 'lexicalized.' A lexicalized concept could be juxtaposed to a concept that is not lexicalized, for example, in a comparison of languages (cf. Lyons, 1977: 235; Talmy, 1985). The concept 'the succession of one day and one night' is thus lexicalized as *døgn* in Norwegian (and Danish), but has no lexical equivalent in English.

New concepts that are given lexical form become part of the lexicon of a language and the process of establishing a new unit in any specific lexicon is commonly referred to as lexicalization. All new words and meanings may thus potentially be lexicalized and the term is often activated in discussions of the integration of loan words, the development of new meanings, and the establishing of idioms as lexical units. Most important in this respect is the concept's relevance to regular word-formation processes, which is discussed below.

Another use of lexicalization indicates a contrast to grammaticalization. Lehmann (1989) compares the two concepts by defining them as processes that move signs in different directions across the border between lexicon and grammar. Moreno Cabrera (1998), on the other hand, defines the relationship between the phenomena as complementary; grammaticalization involves metaphorical abstraction processes, whereas lexicalization has to do with metonymical concretion. Grammaticalization viewed in this light represents a well-developed field of linguistic research, whereas lexicalization thus conceived does not. Hopper and Traugott (1993: 49) briefly refer to lexicalization as the rare "process whereby a nonlexical form such as *up* becomes a fully referential lexical item," thus evoking the difference between grammatical and lexical words.

Finally, a fairly common use of lexicalization refers to the process when morphosyntactic, syntactic, or pragmatic means of conveying information are taken over by lexical forms. One example is Moore (1988), who demonstrates how productive morphosyntactic categories are lexicalized word by word in a situation of language obsolescence; another is Bybee (1985: 18), who refers to examples where once productive causatives or present-tense morphemes are reanalyzed as lexical forms.

Lexicalization and the Lexicon

In broad terms, lexicalization has to do with including new items in the lexicon. Therefore, one's conceptualization of the lexicon is a prerequisite for the use one makes of the term lexicalization. Pawley (1986) makes a point of contrasting the then-dominant structuralist or generative notion of the lexicon with that implied by lexicographers and 'lay lexicographers.'

Since 1986, linguistics has undergone a major shift in the relative amount of interest paid to the lexicon. The 'lexicographers' lexicon' that Pawley pointed to can much more easily be harmonized with the new host of usage-based theories, with cognitive linguistics being the most elaborated framework (cf. Langacker, 1987, 1991, 2000). Here, the mental lexicon is seen as the primary locus of the human language capacity, the network is a metaphor much used to describe its organization, and the distinction between productive rules and stored units is to a large degree erased.

Lexicalization is thus dependent on theories of the lexicon. Lexicalization used within generative theories such as the Lexicalist approach during the 1970s (cf. Bauer, 1988) or within Lexical Morphology during the 1980s evokes a host of theoretical assumptions that cannot easily be compared to those evoked by linguists working within usage-based theories (cf., for example, Svanlund, 2002).

Lexicalization and Word Formation

It is only in relation to regular word formation that lexicalization has been the focus of major research on

a broader basis. Here, Lipka (1977), Bauer (1983), Bakken (1998), and Svanlund (2002) will be used as the major points of orientation. A long-recognized problem when specifying word-formation rules is that they are not easily formulated on the basis of a corpus of established words. Productive word-formation rules produce new complex words, but having come into existence, these words 'step out' of the word-formation grammar. They develop according to other principles and it is these 'other principles' that lexicalization research has focused on.

Lexicalization as Conventionalization

The starting point for the lexicalization of complex words is the nonce formation (Bauer, 1983: 45; Bakken, 1998; Morita, 1995). For a new word form to be established in a socially or mentally defined lexicon, a conventional connection needs to be established between the concept and the new word form; the word must be established as a conventional sign. Lipka (1977: 155) refers to this conventional connection of form and meaning by the term *Hypostasierung* and sees it as the immediate **cause** of the lexicalization process proper as he defines it. Bauer (1983) refers to the phenomenon as 'institutionalization' and, like Lipka, keeps institutionalized and lexicalized words apart. In Bakken (1998), conventionalization is the preferred term for the process of establishing a new unit in the lexicon and, more importantly, conventionalization is seen as the first phase of a gradual lexicalization process, thus making lexicalization a gradient quality of a complex word. Bakken (1998) is inspired by Cognitive Linguistics, where entrenchment is the term translating into conventionalization. Usage is seen as the sanctioning factor that enhances the degree of conventionalization and thus lexicalization. Svanlund (2002) also works within the framework of Cognitive Linguistics, but wants to reserve the term lexicalization for the establishing process. Where other accounts seek to relate the semantics of the complex word to the conventionalization process, Svanlund argues that no logical connection can be established between the degree of conventionalization and the semantics of the complex word. (See Lexicalization as an Aspect of Meaning below.)

Lexicalization as Irregularity

If the lexicon is defined negatively in relation to grammar as Bloomfield (1933) does, it is simply a place where linguistic units are stored rather than generated by rule. A natural consequence of this view of the lexicon is to define lexicalization as a concomitant of irregularity. Bauer (1983) is the most explicit representative of this approach. Since one must accept that nonce formations are produced by word-formation rules, the irregularity of a complex word must occur after the word formation.

It has often been noted that complex words tend to develop in unpredictable directions once they have come into existence. These developments are of different kinds, and Bauer (1983) refers to them as "types of lexicalization," distinguishing between syntactic, semantic, morphological, and phonological lexicalization. Semantic lexicalization (referred to as *idiomatization* by Lipka, 1977) has occurred when, for example, a compound has developed a meaning that is unpredictable given the meanings of its parts. Phonological lexicalization has to do with phonotactic developments blurring the original make-up of the word and morphological lexicalization characterizes complex words with unpredictable inflection. Bauer gives a nuanced discussion of the reasons for the irregularities and is careful to note that whereas some of the discrepancies between the thus lexicalized words and the productive rules are caused by word-internal developments, some are indeed caused by changes in the grammar at large or even changes in the material word (pertains to word meanings). In Bakken (1998: 61–124), it is argued that the lexicalization process essentially is a semantic process, whereby the originally complex word loses its compositional meaning and gradually becomes an arbitrary sign. The occurrence of formal idiosyncracies is seen as secondary, since they allegedly have non-compositionality as a prerequisite.

More importantly, Bakken (1998: 28–35) questions the sharp distinction between regular and irregular word formation, in line with Cognitive Linguistics, and argues that motivation rather than predictability must be the evaluating measure for the description of complex words. It is essentially the theory of the lexicon that is at stake, but the consequences for lexicalization models are obvious. This line of reasoning is followed up by Svanlund (2002) and it is demonstrated how particularly problematic the notion of semantic lexicalization is (see below).

Lexicalization as an Aspect of Meaning

When a complex word is labeled as lexicalized on semantic grounds, the most common measure has been unpredictability. The Norwegian word *barsel* was originally a compound consisting of the elements *barn* ('child') and *øl* ('beer'). It used to refer to the party given on the occasion of a childbirth. It now refers to the confinement itself. This straightforward example would logically be referred to as semantic lexicalization by Bauer, on the grounds that the meaning of the whole is not (any longer) predicted by the

meaning of its parts. However, the whole notion of compositionality is a problematic concept and Svanlund (2002) raises the question of whether any complex word at any time is truly compositional and predictable in meaning. He shows how polysemy, metaphor, and the number of possible relations between elements undermine any naive idea of predictability. On this basis, he presents an alternative model of analyzing the meanings of complex words. The key word here is motivation and one of his main claims is that the model is as applicable to nonce words as to well-established ones, thus demonstrating how the semantics of a complex word is independent of its conventionalization.

Bakken (in press), on the other hand, seeks to justify the connection between conventionalization and word meaning. She concedes that the meaning of complex words can be more or less motivated like Svanlund claims and that a linguist could apply Svanlund's model to both nonce words and well-established words. However, she insists that the importance does not lie not in the conscious analysis of meaning elements, but in the salience of these elements for the language user. Conventionalization enhances automation, and it is in this respect that the non-compositionality of words, i.e., their meaning, could be interpreted as being relevant to the lexicalization process.

Lexicase

R Kikusawa, National Museum of Ethnology, Osaka, Japan

Introduction

Lexicase is a type of European-style dependency/valency grammar, which evolved out of American-style generative transformational grammar. It is a monostratal syntactic theory, which claims that the information for well-structured sentences is implied in each lexical item (or 'word') as its features. Thus, the grammar, such as morphological and syntactic mechanisms and semantic relations, are all described as features carried by lexical items. The assignment of three different types of cases, namely case relations, case forms, and the macrorole actor, is considered to be a prominent part of the grammar (thus the name *lexi-case*).

The theory was developed by Stanley Starosta at the University of Hawai'i, where it has been applied in the study of some 40 languages, mainly Pacific and Asian languages, and English, with some limited work on Greek, Swahili, and Native American languages. In Lexicase, the sentences are analyzed as spoken/written, that is, without going through hypothetical levels, such as 'underlying structures' and 'movements.' This enables the direct comparison of syntactic structures of different languages. Lexicase has also been applied in some morphosyntactic (historical) comparisons, mainly of Austronesian languages, as well as computational language processing.

Regent-Dependent Relationship and Grammatical Description

Being a version of Dependency Grammar, elements constituting sentences are analyzed pair-wise as a sum of regent (or 'head') and dependent relations. A regent carries features that specify what kind of dependents it must take, it may take, and it cannot take. These include syntactic properties and word order, as well as morphological and semantic characteristics of the dependent. When all the regents in a sentence have dependents to meet all such features, then this sentence is well-formed and 'grammatical.'

How this operates with actual language data is illustrated here with a few English *to* prepositional phrases. The locative preposition *to* carries features such as the following: (1) it has to take a noun as its dependent; (2) its dependent noun has to be accusative; (3) its dependent noun has to be locational, and (4) it must be followed by a dependent noun, thus specifying the word category of the dependent, the form of the dependent, the semantic nature of the dependent, and the relative word order between the dependent and itself. In Lexicase formalism, the features that a word carries are listed under each form, as shown in (1). The symbol '?' indicates that whatever follows this symbol is required as a dependent by this form; the feature '@ndex' indicates the respective position of this particular form in a sentence. Both of these symbols are variable and are replaced with appropriate position numbers once an actual sentence or phrase is formed.

(1) *to*

@ndex	... position index of this word
P	... lexical category of this word
? [N]	... required feature of the dependent (a Noun) (i)
? $\begin{bmatrix} \text{N} \\ \text{Acc} \end{bmatrix}$	... required feature of the dependent (an Accusative noun) (ii)
? $\begin{bmatrix} \text{N} \\ \text{loc} \end{bmatrix}$	... required feature of the dependent (a noun indicating location) (iii)
@< ?[N]	... required feature of the dependent (follows the form *to*) (iv)

The phrases *to her* and *to Amsterdam* are both well-structured, since both *her* and *Amsterdam* in these phrases satisfy all the features required by its regent. They are shown in (2), where the variables ('?' and '@') are replaced with appropriate position numbers.

(2a)

to	*her*
1ndex	2ndex
P	N
2 [N]	Acc
2 $\begin{bmatrix} \text{N} \\ \text{Acc} \end{bmatrix}$	loc
2 $\begin{bmatrix} \text{N} \\ \text{loc} \end{bmatrix}$	
1 < 2[N]	

(2b)

to	*Amsterdam*
1ndex	2ndex
P	N
2 [N]	loc
2 $\begin{bmatrix} \text{N} \\ \text{Acc} \end{bmatrix}$	
2 $\begin{bmatrix} \text{N} \\ \text{loc} \end{bmatrix}$	
1 < 2[N]	

On the other hand, in the phrases **to she* and **Amsterdam to*, in each case one of the required features is not satisfied, as indicated with the symbol '*' in (3); the former violating the case requirement and the latter violating the word order requirement. Both are ungrammatical.

(3a)

**to*	*she*
1ndex	2ndex
P	N
2 [N]	Nom
*2 $\begin{bmatrix} \text{N} \\ \text{Acc} \end{bmatrix}$	
1 < 2[N]	

(3b)

**Amsterdam*	*to*
1ndex	2ndex
N	P
1 [N]	
1 $\begin{bmatrix} \text{N} \\ \text{Acc} \end{bmatrix}$	
*2 < 1[N]	

It should be noted that only the relevant features of each word are listed here in (1) through (3), and words are considered to actually carry a far greater number of grammatical features. In Lexicase, the sum of such features of words constituting a sentence determines whether the whole sentence is well-formed, thus the expression 'the grammar comes from the lexicon.'

Word Categories

One of the basic features that words carry is their category, or 'part of speech.' Word categories are determined by their syntactic distribution. For example, if a form occurs as a dependent of and only of a noun, always occurring at the outer edge of an NP (on either side), and if it never occurs as an immediate dependent of a pronoun, then it is analyzed as a Determiner. The eight recognized word categories, namely, Noun (N), Verb (V), Determiner (Det), Adjective (Adj), Adverb (Adv), Pre/Postposition (P), Conjunction (Conj), and Sentence Particle (Sprt), and the regent-dependent relationship among these categories, summarized in Table 1, are considered to be cross-linguistic features. It should be noted that various 'functions' that each word may carry are considered to be separate features from the word category, and are language-specific. For example, a Determiner, defined as above, may carry functions such as indicating a case form, marking definiteness or gender, etc., depending on the language.

Because word categories are determined based on their syntactic distribution, multiple homophones are assumed in a Lexicase grammar. For example, the word 'look' in a sentence *Let's have a look*. with a Determiner preceding it would be analyzed as a noun, while the same form in the phrase *Look at me*. would be analyzed as a verb. The two forms $look_1$ and $look_2$ are analyzed as different lexical items that have a derivational relationship with each other.

An example of a well-formed English sentence 'The man saw a big dog.' is shown in (4) with word category analysis. Elements indicated with parentheses are optional, so that in this example ?([Adj]) means that an Adjective optionally occurs with the form *man*. Therefore, even when the variable '?' is not fulfilled it does not affect the well-formedness of the sentence. Thus, optional features, including word order flexibility, are also considered to be a part of the grammatical information carried by each word.

(4)	The	man	saw	a	big	dog.	
	1ndex	2ndex	3ndex	4ndex	5ndex	6ndex	. . . position index of each word
	Det	N	V	Det	Adj	N	. . . word category of each word
		1[Det]	6[N]			4[Det]	. . . dependent required by each word
		?([Adj])	2[N]			5([Adj])	. . . dependent required by each word

Three Cases – Case Relations, Case Forms, and the Macrorole

In a Lexicase grammar, nouns are considered to carry three different 'cases,' namely, case relations, case forms, and the macrorole. The assignment of these different types of cases enables various language-internal and cross-linguistic grammatical generalizations to be captured, especially generalizations shared by both ergative and accusative types of languages. In a sentence, every noun carries a case relation (or, the feature +prdc [predicate], which is considered to grammatically commute with case relations) and a case form, while only one noun in a clause carries the macrorole.

Table 1 Word categories and dependency relations

	Verb	*Noun*	*Pre/post-position*	*Adverb*	*Adjective*	*Determiner*	*Conjunction*	*Sentence particle*
Verb	+	+	+	+	−	−	+	+
Noun	+	+	+	−	+	+	+	+
Pre/post position	+	+	+	−	−	−	+	+
Adverb	−	−	−	−	+	−	−	−
Adjective	−	−	−	+	−	−	−	−
Determiner	−	−	−	−	−	−	−	−
Conjunction	+	+	+	+	+	−	+	−
Sentence particle	−	−	−	−	−	−	−	−

Each column indicates whether the word category indicated in the top row (shown in italics) can be a dependent of the word category indicated in the left column (shown in bold). The symbol '+' indicates that it can, and the symbol '−' indicates that it cannot.

There are five case relations:

1. Patient (PAT)
2. Agent (AGT)
3. Locus (LOC)
4. Means (MNS)
5. Correspondent (COR)

Among these, PAT is required by every verb (including all intransitive verbs) as its complement (*Andrew* in (5), *John* in (6) and (7)), while AGT is required by every transitive verb as its additional complement (*Mary* in (6)).

Case forms refer to any morphological and/or syntactic configurations that characterize a set of nouns in a sentence. The number of case forms that occur in a language may differ depending on each specific language. The major case forms are labeled as follows:

- Nominative (Nom): The case form that indicates both the [PAT] of intransitive sentences and either the [PAT] or the [AGT] of transitive sentences. This case form is shared by all languages. Note that by definition this covers also what is often referred to as 'absolutive.'
- Accusative (Acc): The case form that marks the [PAT] of transitive sentences in an accusative language.
- Ergative (Erg): The case form that only marks the [AGT] of a transitive clause. However, if the form also marks instruments, it is labeled as Instrumental (Ins), and if it marks adnominal possessors, it is labeled as Genitive (Gen).

Unlike case relations and case forms, which are assigned to every occurring Noun, there is only one macrorole in a sentence, 'actor' ([actr]), which is assigned to the same noun as the [AGT] of a transitive clause or the [PAT] of an intransitive clause.

Roughly speaking, the notion [PAT] corresponds to the thematic roles patient and theme in Case Grammar, and the theta role patient in Government and Binding theory. The Nominative case form roughly corresponds to what is often referred to as the '(grammatical) subject,' and the notion [actr] to what is often referred to as the 'logical subject.' Some sentence examples with three cases indicated are shown in (5) through (7). The case form of the word *Mary* in (6) cannot be determined from the form of the word itself, but is determined by its immediate postverbal word order and by the potential alternation with an accusative pronoun *she*.

(5)	He	ran.	
	N	V	. . . word category
	Nom	-trns	. . . case form (N), transitivity (V)
	PAT		. . . case relation
	actr		. . . macrorole

(6)	Mary	hit	him.	
	N	V	N	. . .word category
	Nom	+trns	Acc	. . . case form (N), transitivity (V)
	AGT		PAT	. . . case relation
	actr			. . . macrorole

(7)	He	was	hit	by	her.	
	N	V	V	P	N	. . . word category
	Nom	-trns	+adjc		Acc	. . . case form (N), transitivity (V)
	PAT					. . . case relation
	actr					. . . macrorole

The description of certain grammatical characteristics, including the actancy system (whether a language is ergative or accusative), agreement patterns, and patterns of control are described using these three cases. For example, an ergative system is defined in Lexicase as one where the [PAT] of both transitive and intransitive sentences is marked by the same case form, while an accusative system is one where the [actr] of both transitive and intransitive sentences is marked by the same case form.

The Application of Rules in Lexicase Grammar

Word categories and case types are the basic features that are employed to analyze and describe sentences. However, various rule types are employed to capture generalizations within the language and to enable cross-linguistic generalizations to be made.

For example, Redundancy Rules (RRs) and Subcategorization Rules (SRs) are implicational statements about relations between features. The former simply states that if a word carries one or more particular features, it will also contain certain other features. For example, if a word carries the feature [+prnn] (pronominal), then it must carry the feature [N] (Noun). The latter is the reverse of the former. For example, if a word carries the feature [N], then it may be subcategorized into either [+prnn] (pronominal) or [-prnn] (nonpronominal). Subcategorization Rules also contain what can be referred to as 'Inflectional Subcategorization Rules,' which break up stems into paradigms of inflected forms. For example, if a word is [-prnn] (nonpronominal, which implies that it is a subcategory of a Noun), it is inflected into [±plrl] (plural or nonplural).

Linking Rules (LRs) copy the index of the dependent word onto the regent matrix as the value of one of its contextual features (the replacement of the symbols '?' in the regent with the numbers that fill the symbols '@' in (2) and (3)). Chaining Rules are also used to copy indices from items in higher or lower domains to satisfy contextual features in cases

Figure 1 Relationship among lexicase rules.

where the dependency relationship is between words in different dependency domains. Chaining Rules (CRs) include the index mapping related to infinitival complementation ('control') and displacement ('wh-movement').

In addition, there are Derivational Rules (DRs), which state analogical relationships among subsets of lexical entries and are used to account for the active-passive relationship, and 'raising' to subject and object, etc.; Morphological Rules (MRs), which specify morphological marking of inflectional features; and Inflectional Redundancy Rules (IRRs), which specify agreement relationship and word order patterns. The relationship among these rules is shown in Figure 1.

Lexicography: Overview

P Hanks, Brandeis University, Waltham, MA; USA and Berlin-Brandenburg Academy of Sciences, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Lexicography is the art or craft of writing dictionaries. In contrast to lexicology (*see* **Lexicology**), which is the theoretical study of words, their use, and their meaning, lexicography is a practical activity that involves compiling an inventory of the words in a language (or some particular subset of them) and saying something about each of them. Lexicographers were described by Trench (1858) as "the inventory clerks of language." Their primary duty is to collect an inventory of all the words in the language (or a selected subset), and to say something about each of them. There are many different kinds of dictionaries, giving many different kinds of information about words. The main ones are: (1) scholarly dictionaries of record; (2) practical dictionaries for everyday use; (3) pedagogical dictionaries; (4) dictionaries of linguistic phenomena such as slang or idioms; and (5) special-subject dictionaries. All the foregoing kinds are monolingual. To these we must add: (6) bilingual dictionaries; (7) onomasiological dictionaries (thesauruses, synonym dictionaries); and (8) term banks. There are also hybrid dictionaries, for example, monolingual dictionaries for second-language learners with marginal glosses in a relevant foreign language.

Four issues of general principle that must be considered for all serious types of dictionaries in any language are: (1) breadth, not depth; (2) consistency; (3) descriptive versus prescriptive approach to the language; and (4) historical versus synchronic approach. The third of these, in particular, is controversial: there are many circumstances in which a dictionary, rightly or wrongly, is expected to play a prescriptive role in a language.

General procedures for many kinds of lexicography include collecting, 'tokenizing,' and 'lemmatizing' words. Having established a draft word list, the lexicographer must decide what to say about each word. This includes decisions about (1) orthography of both the headword and inflected forms; (2) guidance on pronunciations; (3) word-class classification (part of speech); (4) definition writing; (5) examples; (6) phraseology; (7) disputed points of usage; and (8) etymology and word histories.

Brief History of Lexicography

Lexicography had its beginnings in the ancient civilizations of the Middle East (*see* **Bilingual Lexicography**) and ancient Chinese civilization (*see* **Chinese Lexicography**). In ancient Greece there were already dictionaries in the fifth century B.C. These were compiled to explain words used by Homer and other writers from the Archaic period, which had become rare or obsolete by the Classical period. Classical Greek lexicography was exclusively monolingual until quite a late period (*see* **Greek Lexicography, Classical**). It was left to the Romans to introduce bilingual lexicography (Latin → Greek, Greek → Latin), from the first century B.C. onward.

In many of the languages of Europe, the origins of lexicography can be traced back to interlinear glosses in medieval manuscripts (*see*, for example, **English Lexicography**, **German Lexicography**). Monks noted the vernacular equivalents of unfamiliar Latin words on the manuscript as an aid to understanding the text. In some monasteries, the glosses were subsequently collected and arranged roughly in alphabetical order in a separate manuscript. The development of European dictionaries as we understand them today, however, had to await the invention of printing technology in Germany by Johannes Gutenberg in 1450. Printed dictionaries became practical tools that could be mass-produced by the hundreds and thousands, enabling identical information about words to be disseminated extremely rapidly throughout a community. A major milestone in the development of European lexicography was the publication in Paris in 1531 of the *Dictionarium, seu Latinae linguae thesaurus* by the great Renaissance scholar and printer Robert Estienne (Robertus Stephanus). In 1538 he followed this with a Latin–French dictionary and in 1539 a French–Latin dictionary. These magnificent works remained unchallenged as authorities for over two hundred years and were the source of innumerable derivatives and revisions. Bilingual dictionaries played a major part in the revival of learning (Latin and Greek) during the Renaissance and an equally important part, first in the spread of Italian and French culture into northern Europe, and subsequently in the interplay of languages that was characteristic of Europe from the 15th century to the late 20th century, at which time, once again, an international lingua franca (English this time, not Latin) was to emerge. European dictionaries of the 15th and 16th centuries were of two kinds: those that played a role in the learning of Latin and those that were

designed to explain the words of one vernacular in terms of another. Many of these early printed dictionaries displayed great energy, learning, and sophistication, although an examination of them also provides a reminder of the important part played by the linguistic philosophy of the Enlightenment (17th and 18th centuries) in developing lexicographical standards of accuracy and consistency. Sixteenth-century dictionaries were full of information, but much of it was anecdotal and discursive. Balance and consistency were not among the lexicographical virtues of Renaissance dictionaries. Multilingual dictionaries were also popular during the Renaissance; valiant attempts were made to represent the meaning of words in one language by equivalents in several others. Only gradually did people come to realize how difficult it is to represent one language in terms of another. Languages do not map easily onto one another, and trying to map three or more languages onto each other is an impossibility, except in the case of superficial equivalents such as terms for artifacts in a technology that is shared by many linguistic cultures.

During the 18th century, large dictionaries were compiled in all the languages of Europe that were not the tongue of an oppressed minority. Academies were established with the aim of preserving the purity of vernacular languages (*see* **Academies: Dictionaries and Standards**). Great advances were made in data collection. (The aim was to collect and define all the words of a language, not just the 'hard words.') Scientific standards of definition writing were pursued. Some 18th-century lexicographers made strenuous efforts to implement the 'substitution principle,' a notion that can be traced back to Leibniz's dictum that two things are the same if the one can be substituted for the other without affecting the truth value (*salva veritate*). The idea was – and is – that a definition should be substitutable in any context for the word being defined (the *definiendum*). The substitution principle, coupled with unthinking reductionism (according to which every sense of every word is defined as an independent linguistic entity, rather than as part of a phraseological whole) is responsible for some of the convolutions still to be found in present-day dictionaries, for example in the definitions of English reciprocal verbs:

> **meet** (sense 2): to come into or be in conjunction or contact with (something or someone else or each other).

This definition may be convoluted, but at least it is an attempt to capture the reciprocal syntactic potential of the verb, as in examples 1–5 below. Some other English dictionaries present these as separate senses, while others ignore the syntax completely or indicate only 'transitive' and 'intransitive.'

1. John met Sally.
2. Sally met John.
3. John and Sally met.
4. John and Sally met each other.
5. John and Sally met with each other.

Eighteenth-century dictionaries saw their role not only as recorders of the words of a language, but also as reinforcers of 'correct' usage, to warn against barbarisms. Thus, Johnson (1755) included citations from "the best authorities" to show how English words are used, and included comments on words that he disapproved of (e.g., "**clever**: a low word"). During the 19th century, a shift from such prescriptive attitudes to scientific descriptive principles occurred in many important European lexicography projects.

The proposal by Sir William Jones in 1786 that Sanskrit, Greek, Latin, and other languages were "sprung from some common source which, perhaps, no longer exists" had a profound effect on scholarly lexicography. Although the American lexicographer Noah Webster (*see* **American Lexicography**) rejected the Indo-European hypothesis, preferring to believe that English words were derived from 'Chaldee,' scholarly lexicography in Europe throughout the 19th century devoted much energy to discovering the Indo-European roots of everyday words and establishing cognate relationships among words in different languages. Etymology, which in the 18th century had been a matter of wild guesswork, became a painstaking scientific discipline and came to dominate lexicography (*see* **Etymology**). The task of the scholarly lexicographer in all the leading languages of Europe was seen partially, if not primarily, as a historical one: not only to define the meaning of words but also to trace their origins. In 1864 Webster's successor Noah Porter and his etymologist C. A. F. Mahn quietly dropped 'Chaldee' and brought the leading American English dictionary into line with the rest of Western scholarship.

The establishment of lexicography as a scholarly discipline on historical principles led to the establishment of scholarly dictionaries of record for many languages. Also in the 19th and 20th centuries, large scholarly dictionaries of ancient and medieval languages began to be compiled, presenting a detailed account of the recorded vocabulary of major languages at earlier historical periods. Some of these great scholarly projects continued for many decades. The culmination of historical and in particular

Indo-European lexicographical scholarship is still being worked out. In 1949 Carl Darling Buck published *A dictionary of selected synonyms in the principal Indo-European languages*. At the University of Leiden, a major project is currently underway with the goal of creating an Indo-European etymological database on the Internet and, eventually, compiling a new Indo-European etymological dictionary, designed to supersede Julius Pokorny's *Indogermanisches etymologisches Wörterbuch* (1959).

In the 20th century another school of lexicography grew up, the purpose of which was to explain the meaning and use of words in the contemporary language, relegating etymology and obsolete senses to a subsidiary role. Historical principles were superseded in these dictionaries by synchronic principles, more suitable for practical everyday works. The first work to make this distinction explicitly was Funk and Wagnall's *Standard dictionary of the English language* (1893). Some but not all American dictionaries followed Funk and Wagnall's lead, for example the *American College dictionary* (1949), its successor the *Random House dictionary* (1964), and the *American Heritage dictionary* (1969). Others, including the Merriam-Webster dictionaries, clung to the more traditional historical principles. Among British and Australian one-volume dictionaries, it is now standard to follow synchronic principles rather than historical principles. One-volume dictionaries of the English language (both historical and synchronic) characteristically focus on explaining meaning, with comparatively few examples. In other languages, for example German and Greek, the focus of one-volume dictionaries is often very much more on phraseology and usage, with many more examples of usage than are found in one-volume English dictionaries and comparatively less space devoted to definitions. In Russia, dictionary compilation was associated with important developments in linguistic theory (*see* **Russian Lexicography**), for example the meaning = text theory of Mel'čuk (*see* **Mel'čuk, Igor Aleksandrovic (b.1932)**).

Beginning in the late 1980s, lexicography began to respond to the opportunities offered by computer technology, in particular the use of computers to collect and process evidence of word use on a very large scale (*see* **Corpus Lexicography**).

Typology of Dictionaries

There are innumerable works calling themselves 'dictionaries' in almost every language in the world that has a literature. Indeed, modern lexicography also plays a major part in recording the vocabulary of and establishing written norms for languages that do **not** have a literature. These works are extremely heterogeneous: some of them have nothing in common other than the word 'dictionary' in the title. Others are clearly members of the same family of reference works. A typology of dictionaries may be attempted, identifying the following types: scholarly dictionaries of record, practical dictionaries for everyday use, pedagogical dictionaries, dictionaries of slang and/or idioms, special-subject dictionaries – all of which are monolingual and explanatory in nature – along with bilingual dictionaries, onomasiological dictionaries, and term banks. In addition, there are various less frequent classes, for example hybrid works such as monolingual dictionaries for second-language learners with marginal glosses in a relevant foreign language.

Scholarly Dictionaries of Record

The 19th and 20th centuries saw an explosion of scholarly lexicographical activity. Every language in the world that has an established literary tradition now has (or will soon have) a major dictionary of record, recording the vocabulary of the language and usually but not always organized on historical principles, with plentiful citations illustrating usage and supporting the definitions. Classic examples of great historical dictionaries are the *Oxford English dictionary* (OED) (discussed in **English Lexicography**), the *Trésor de la langue française* (*see* **French Lexicography**), and the *Deutsches Wörterbuch* of the brothers Grimm (*see* **German Lexicography**).

The present encyclopedia includes articles on the history and current state of the art of lexicography in all the world's major languages. There are also articles on major areas of historical lexicographical scholarship (*see* **Old English Dictionaries**, **Middle English Dictionaries**, and **Old French Dictionaries**). In other cases, historical dictionaries are surveyed in the relevant national articles (*see*, for example, **Dutch and Flemish Lexicography**, **German Lexicography**).

As a subgroup of the category of scholarly dictionaries, dictionaries of etymology and word history should also be mentioned. These range from popular works such as Chantrell's very readable *Oxford dictionary of word histories* (2002) and Picoche's *Dictionnaire étymologique du français* (1992) to larger works of scholarship such as Kluge's *Etymologisches Wörterbuch der deutschen Sprache* (1st edn., 1883; 24th edn., 2002), the Dutch *Etymologisch*

woordenboek by P. van Veen and N. van der Sijs (1997), V. Machek's *Etymologický slovník jazyka Ceského* (1997), and Pokorny's *Indogermanisches etymologisches Wörterbuch* (1959).

Practical Dictionaries for Everyday Use

Despite the high cost of compiling a dictionary, most languages offer a range of choices of one-volume dictionaries, varying greatly in size and scope. In size, they range from small pocket books giving simple definitions by synonym and spelling dictionaries listing only word forms (together with occasional comments on points of orthographical difficulty), to large and ambitious works that give detailed information about many aspects of word meaning and word use, as well as facts about the world, such as famous people and places or the distribution and habitat of a plant or its New Latin name. The emphasis in practical dictionaries nowadays is often on presenting a wealth of complex facts about words in a way that is as accessible as possible for users. Lexicographers of an earlier generation appear to have been less concerned with user-friendliness. For example, the first edition of the *Concise Oxford dictionary* (1911) seems very dense and hard to use when compared with the 10th edition (1999), where a great deal of careful planning went into the page design and layout, as well as the selection of information. The compilers of such dictionaries are faced with choices at each step of the work, to which the answer is not always obvious. For example, should a practical dictionary record rare and obsolete words? Some dictionary publishers take the view that this is the *raison d'être* of a practical dictionary. No user, it is argued, will look up a very ordinary, familiar word, so as little space as possible should be wasted on such words. The likelihood that a word will be unfamiliar and therefore looked up in a dictionary (if encountered by a reader in some text) increases with its rarity, until the point is reached where the word is so rare that no one will ever encounter it. Another decision concerns the presentation of grammatical information. Facts about such matters as complementation patterns, countability, and selectional preferences are the linguist's stock in trade, but the practical lexicographer has to bear in mind that many ordinary users are not trained linguists and (especially in the English-speaking world) may actually be hostile to grammar. A judgment must be made whether anything at all should be said about each grammatical point concerning each word, and, if the answer is yes, how to present it. Often, exemplification, on the basis of which a user can make analogies, is considered to be a more effective explanatory technique than an abstract metalanguage.

Pedagogical Dictionaries

There are two main kinds of pedagogical dictionaries: those compiled for foreign learners of a language and those compiled for schoolchildren who are native speakers. Dictionaries for foreign learners are often formidable works of scholarship, with a much greater emphasis on syntax and usage than is usual in dictionaries for native speakers (*see* **Learners' Dictionaries**). Here, the pedagogical lexicographer has to decide whether the emphasis should be on helping the user to 'encode' or 'decode' the language. Many foreign learners use dictionaries to help with language encoding – i.e., to write naturally and idiomatically in the foreign language. A dictionary designed for encoding use typically has a smaller word list and many more examples of usage than one for decoding use. An encoding dictionary rigorously eschews eccentric or fanciful usage and is sensitive to selectional preferences.

Dictionaries for schoolchildren are often nothing more than simplified versions of small dictionaries for adults. However, there are also some fine examples of dictionaries that take their pedagogical function seriously, not only explaining the meanings of words in suitable terms and focusing on 'hard words' but also presenting facts about grammar selected for the appropriate age group (*see*, for example, **English Lexicography**).

Dictionaries of Slang, Idioms, Etc.

Good slang dictionaries (*see* **Slang Dictionaries, English**) in many ways resemble the great scholarly dictionaries. Great efforts are made to collect citations from a vast variety of sources, many of them ephemeral, and a selection of the citations is presented in the dictionary itself, often with bibliographical information. The definitions and examples in slang dictionaries are of the greatest importance, because (unlike general dictionaries) many of the headwords will be quite unfamiliar to users.

Dictionaries of idioms (*see* **Idiom Dictionaries**) are more often aimed at foreign learners than at native speakers. They are classified here with slang dictionaries, because their aim is to collect and explain a specific subset of the vocabulary, rather than the whole language. The same is true of dictionaries of phrasal verbs.

There are several other kinds of dictionary that focus on subsets of the vocabulary of a language,

for example dictionaries of loanwords such as the *Dictionary of European Anglicisms* (2001).

Special-Subject Dictionaries

The number of subjects of which dictionaries have been made is vast, ranging from huge dictionaries of medicine and law to quite small dictionaries of particular sports or games. Typically, special-subject dictionaries differ from general dictionaries in that they give more detailed and discursive encyclopedic information about each term, rather than merely a definition, while at the same time including little or no linguistic information. The focus is on objects and concepts, rather than on usage and linguistic behavior.

Bilingual Dictionaries

Bilingual dictionaries are typically practical tools for interlingual communication and learning, rather than scholarly studies (*see* **Bilingual Lexicography** and **Dictionaries**).

Onomasiological Lexicography

A distinction can be made between semasiological and onomasiological dictionaries. Semasiological dictionaries consist of an alphabetical list leading the user from the word to its meaning(s), which is the principle characteristic of the dictionary types discussed up to now in this article. By contrast, the idea behind an onomasiological dictionary is to help the user to find the appropriate word for a particular meaning or concept. Various techniques are used in the attempt to achieve this aim. The classic example of an onomasiological dictionary is Roget's Thesaurus, in which words are arranged in hierarchies under more general terms (**hypernyms**, also called **superordinates**). Thus, the terms *sofa* and *settee* may be found listed under *furniture* (*see* **Thesauruses**). Another techinique is to provide lists of synonyms and antonyms for a headword, in the hope that one of them may be the term that the user is looking for. An example of an onomasiological dictionary that helps users to discriminate between near synonyms is McArthur's *Longman lexicon* (1981).

Another kind of onomasiological lexicography is the compilation of terminological databases (*see* **Terminology and Terminological Databases**). In a world of increasingly complex engineering and technology in a multilingual environment, vast on-line terminological databases serve vital needs for standardization of teminology for many specialist communities.

Dictionaries of Rare and Endangered Languages

The need for a lexical inventory is also felt by languages that have no large literary tradition. A great deal of lexicographical work is currently being done on rare and endangered languages. Lexicographical tools for field linguists to use in compiling dictionaries and corpora of rare languages are available, for example, SIL's Toolbox. The motivation for such dictionaries is various: sometimes, the lexicographer is trying to establish a written standard for a language that previously was not written down. Sometimes, in the case of severely endangered languages, the motivation is simply to record the lexicon and phraseology of the language before it is lost forever. Much more often, however, the motivation for such a dictionary allies scholarship to practical needs: providing access for speakers of a rare language to the wider world and to modern facilities, markets, and technology, plus the more traditional motivation of providing missionaries with a tool to help them to do good works, translate the Bible, and preach the word of God to speakers of a minority language. Such dictionaries are inevitably bilingual, with varying degrees of emphasis on the source language and the target language, depending on the local circumstances. Simpson (1993) discussed the objectives and methods for dictionaries of Australian Aboriginal languages. The target language of such dictionaries is typically English, although in certain geographical locations it may be Russian, Spanish, or Portuguese (*see* **Bilingual Lexicography**; **Endangered Languages** for further discussion).

Principles of Lexicography

The needs, problems, and opportunities presented by the lexicon of each language differ, and where appropriate these are discussed in the articles devoted to the lexicography of each language. Four general issues of principle, applicable to most or all types of dictionary in most or all languages, may be discerned. These are: (1) breadth, not depth; (2) consistency; (3) descriptive versus prescriptive approach to the language; and (4) historical versus synchronic approach.

Breadth, Not Depth

Unlike other kinds of scholarship, lexicography generally aims at breadth rather than depth. A dictionary does not say everything that could possibly be said about a particular word or linguistic phenomenon.

Instead, it tries to present a reasonably comprehensive inventory of the vocabulary and to state just those facts that are most salient or most relevant about each word. This inventory may be a list of all the words of the language that are in common use, all the words that a learner needs to know, all the words relevant to a particular subject, or all the words ever used in the literary record of a particular language. But as far as the entries themselves are concerned, it is necessary for dictionaries to idealize – and often simplify – word meaning and word use. To attempt to account in detail for all possible uses of words would be to attempt the impossible, for usage is open-ended and shades of meaning are determined by context. Furthermore, if a dictionary presents too much information about a particular word, there is a danger that the user may not be able to see the woods for the trees. There are principled as well as practical reasons for dictionaries to be economical with space.

Consistency

Having collected the inventory, the lexicographer must say something about everything in it and must aim at consistency of coverage and presentation or wording. The user of a dictionary is entitled to expect that all differences in the presentation represent some differences in the language, i.e., stylistic variation for its own sake is avoided. For this reason, unlike other kinds of writers, lexicographers aim to repeat the same forms of words (in definitions and etymologies) wherever possible, so that only real differences in meaning or use are reflected in the wording. It is no good saying "of or pertaining to X" at one entry and "relating to Y" at another entry, if "of or pertaining to" and "relating to" are intended to convey the same message. More seriously, consistency of coverage is always the goal in modern dictionaries. Allied to this is the principle of 'consistency of sets': the selection of entries and the definitions of a set of related items should be worded, as far as possible, consistently. A modern dictionary will include entries for all chemical elements, even rare ones, on the principle of consistency of sets. On the other hand, it would be quite impossible to include entries for all possible chemical compounds, so some additional principle – e.g., common usage – must be invoked. Computer technology is a great help here: it enables the chief editor of a new dictionary to divide up the work by topic rather than in alphabetical order and to assign the work to relevant specialists, so that, for example, the chemistry editor can make a reasonable selection of terms denoting compounds; the medical editor can define all the bones of the body, all the organs, all the physiological processes, all the diseases; and so on in accordance with a systematic policy, without being hampered by the need to work in alphabetical order (or to use cumbersome card indexes), as was the case before computer text processing became commonplace.

Consistency of treatment is all very well, but there is also a danger that consistency may become a false god, forcing the members of a lexicographical team to distort subtle linguistic differences in the name of consistency. The lexicographical apparatus available to the members of a lexicographic team must be powerful enough to reflect subtle differences in linguistic facts, and team members must know how to use it. For example, in an English dictionary, for the sake of economy of space, the word *lexicographical* may be listed as a rare variant of *lexicographic*. No separate entry is necessary. But the same treatment certainly cannot be accorded to *historical* and *historic* or *economical* and *economic*. So much is obvious. However, other cases may be more difficult to decide. What, for example, is to be done about *evangelistical*? Should it be treated simply as a rare variant of *evangelistic*, or is there a subtle difference of meaning, requiring separate entry? Careful scrutiny of the evidence is required, rather than application of a rule by rote in the name of 'consistency.'

Descriptive or Prescriptive?

Most modern lexicographers agree that their job is to describe the language, not to legislate about right and wrong. Those few who have, from time to time, set themselves up as pundits and pontificators have had remarkably little success in halting the endless process of language change. Some changes in language may be a matter for regret, while others may be welcome. However, the lexicographer can only hope to describe what is going on in the language, not to change it. This is a very different principle from the principles that motivated 17th- and 18th-century European lexicographers, for example, the Académie Française (*see* **Academies: Dictionaries and Standards**). The lexicographers of the Enlightenment had explicit goals to 'fix' the language, to set standards of correct usage, and to combat any decline in those standards.

It fell to Samuel Johnson to abandon his original commission to 'fix' the English language and to draw attention to the impossibility of such a goal:

> When we see men grow old and die at a certain time one after another, from century to century, we laugh at the elixir that promises to prolong life to a thousand years;

> and with equal justice may the lexicographer be derided, who being able to produce no example of a nation that has preserved their words and phrases from mutability, shall imagine that his dictionary can embalm his language, and secure it from corruption or decay. . . . With this hope, however, academies have been instituted, to guard the avenues of their language, to retain fugitives, and repulse intruders; but their vigilance and activity have hitherto been vain; sounds are too volatile and subtle for legal restraint; to enchain syllables, and to lash the wind, are equally the undertakings of pride, unwilling to measure its desires by its strength. (*English dictionary, 1755, Preface*)

Nevertheless, no matter how vehemently the lexicographer may agree with Johnson and protest, with Clarence Barnhart in the General Introduction to the *American College dictionary* (1949), that "it is not the function of the dictionary-maker to tell you how to speak, any more than it is the function of the mapmaker to move rivers or rearrange mountains or fill in lakes," it must be acknowledged that many users will inevitably treat a dictionary as if it were a prescriptive tool, looking to it for guidance on good usage. As Jess Stein wrote in the preface to the first edition of the *Random House dictionary* (1966):

> Since language is a social institution, the lexicographer must give the user an adequate indication of the attitudes of society toward particular words or expression, whether he regards those attitudes as linguistically sound or not.

Various expedients have been devised to deal with this problem, of which the most successful is to comment explicitly on disputed points of usage, discussing the evidence in a usage note (see later section on 'The Internal Structure of Dictionary Entries').

Historical Principles or Synchronic Description?

As a general rule, scholarly dictionaries of record are compiled on historical principles – that is to say, they first record the etymology of each word in the language (*see* **Etymology**), then define the earliest sense of the word, and then go on to outline the word's semantic and grammatical development from that point on. Large dictionaries of record also give archaic and obsolete spellings. Because languages are unstable, i.e., word forms, conventions of usage, and meanings change over time, many entries in the great scholarly dictionaries of literary languages start with a sense that is now obsolete. Current senses are sometimes buried in the middle of an article or near the end. To take a simple example, the word *camera* in English is now used almost exclusively to denote an apparatus for taking photographs, but formerly it meant 'a small room' (the sense of the Latin word that was taken into English in the 17th century) or 'a legislative chamber' and, more specifically, 'the treasury department of the papal curia.' Placing these three senses first in the entry for the English word *camera* raises interesting theoretical questions about the nature of literal word meaning. The methodology of historical principles is elaborated in Burchfield (1989).

'Synchronic principles' – placement of the modern meaning of each word first – may seem to be no more than a matter of common sense. But in many cases it turns out not to be easy to decide what is 'the modern meaning.' For example, it is not clear whether the 'modern meaning' of the English word *oasis* is (1) a haven of calm in a big city or other hectic place or situation, or (2) a fertile spot in a desert. (1) seems to be at least as common as (2). For practical purposes, it might be thought desirable to place (1) first, since few English speakers live in a desert. Appeals to etymology are often made, but if etymology were a good guide to the literal meaning of modern words, then the first meaning of *camera* would be 'a small room' and the first meaning of *dope* would be 'a thick varnish.' To decide which meaning to place first, the synchronic lexicographer needs to take a principled view about what counts as literal meaning and to balance the (sometimes conflicting) claims of frequency, etymology, concrete versus abstract, cognitive plausibility, and other factors. Synchronic principles are sometimes expressed in terms of 'arranging senses in order of frequency,' but in fact this is never done. The best that a synchronic lexicographer can do is to start with a sense that has a reasonable claim to be literal and currently common and then to arrange the other senses in some sort of coherent order thereafter. Dictionary entries have a discourse structure of their own. Different senses of a word are not merely mutually exclusive alternatives. Rather, the entry for a polysemous word is to be read as a whole, in which senses (2) and (3) are influenced by and draw on what has been stated at sense (1). Thus, it is easier to explain and understand reference to an *oasis* of calm in a big city if it can be read as a secondary sense, a conventionalized metaphor exploiting a primary definition that describes an oasis as a tranquil green location in a desert.

Lexicographical Procedures

Collecting the Evidence

As already mentioned, it is now widely accepted that the central part of the lexicographer's task is to

compile an inventory, collecting evidence for words and showing how they are actually used.

The traditional method of collecting evidence for a dictionary is to set up a reading program, i.e., for readers to read books or journals and to transcribe citations for interesting words onto small slips of paper, which are then stored in a filing cabinet before being examined as evidence for a possible definition, in some cases many years after the slip was first collected. This methodology is extraordinarily slow, expensive, and labor-intensive; nevertheless, it has been the methodology that has supported most of the great historical dictionary projects of European languages. All this is now changing with the increasing emphasis on collecting electronic text archives. These can be processed computationally, providing a concordance for **all** uses of a word in all the texts that are accessible in electronic form. Before long, it will be possible for historical lexicographers to see how the usage of great writers of the past compared with the everyday conventional usage of their day, insofar as ordinary nonliterary texts from the relevant period survive and have been put into machine-readable form. This may be expected to lead to new developments in historical lexicography.

Large practical dictionaries often place considerable store on explaining technical terms and technical senses of words in science and technology, medicine, law, economics, business, sports, and so on. For such dictionaries, specialized reading programs with a focus on textbooks and manuals in various disciplines are sometimes set up.

The growth of electronic corpora since the mid–1980s has had a profound effect on the collection of lexicographical evidence (*see* **Corpus Linguistics, Corpus Lexicography, Corpus Approaches to Idiom**). A modern corpus containing hundreds of millions of words of text, with a good concordance program, can provide instant access to more evidence than any lexicographer could possibly use, showing how each ordinary word is ordinarily used in the language. Statistical tools such as the Sketch Engine (*see* **Computers in Lexicography**) help the lexicographer to decide which word associations or collocations are important and which can be safely ignored. In addition to this, the Internet itself can now be used as a corpus, providing evidence for unusual as well as normal uses of words, on the basis of billions of pages of electronic text (see Grefenstette and Kilgarriff, 2003; Church and Mercer, 1993). As mentioned above, these techniques are equally applicable to historical dictionaries, provided that the relevant texts are available and accessible in machine-readable form.

Identifying Words: Tokenization, Lemmatization

Once words have been identified, their usage and meaning can be studied. But what is a word? To readers of English, Spanish, or French, it seems obvious that a word is a string of letters bounded by a space or a punctuation mark. It is easy to overlook how reliant on an artificial cultural convention this notion of word boundaries is. Establishing word boundaries is a problem for computational language processing in German and many other languages written alphabetically, not to mention languages such as Chinese and Japanese, which have other writing systems. Two examples of the problem may be given from German. On the one hand, German prints as a single 'word' some items that in English require at least four 'words' – for example, *Binnenschifffahrtsstraßenverkehrsordnung* 'inland waterways traffic regulation.' On the other hand, certain verbs in German are 'separable,' i.e., they contain a particle that is separated from the root verb in finite contexts, e.g., *abfahren* 'drive away' is found in finite contexts such as *Er fuhr langsam ab* 'he drove slowly away'; thus a single 'word' is printed as two 'words' at opposite ends of the sentence. Such conventions present interesting challenges for tagging, sorting, and grouping lexicographical evidence. Whereas a concordancing program for English can rely on spaces and punctuations marks as indicators of word boundaries and simple string matches for finding different inflected forms of a word, for German it is absolutely necessary to pre-process a corpus by 'lemmatizing' it, i.e., by identifying all the inflected and separated forms of each word and grouping them together, also identifying boundaries between bound morphemes, i.e., word boundaries that are not represented in written texts by a space.

There are at least four different senses of the word *word*. To avoid confusion, the term is often avoided altogether in technical writing about language, being replaced with more specific terms. The four main competing senses of *word* are:

1. (synonym: *type*) A unique spelling form considered as an abstract category; a particular string of letters, without any reference to the meaning of the string. A type is always just a single type, no matter how often it is used or how many senses it may have.
2. (synonym: *token*) Any one occurrence of a type in a text. The text *the cat sat on the mat* contains six tokens, but only five types, because there are two tokens of the type *the*.
3. (synonym: *lemma*) A further abstract category, consisting of all the different inflected forms of a

word type grouped together under a single heading. Thus, the English verb lemma *take* consists of five types: *take, takes, taking, took, taken*. In highly inflected languages such as Czech, 30 or 40 different types may be grouped together as inflected forms of a single lemma.

4. (synonym: *lexical item*) A minimal meaning-bearing unit of language. In this sense, *word* overlaps with 'bound morphemes' such as *un-* and *pre-* on the one hand and with 'multiword expressions' such as *gas burner* and *air cushion vehicle* on the other hand.

Dictionaries typically record (3) and (4), grouping words into lemmas and also recording bound morphemes, together with a selection of multiword expressions (*see* **Word**).

Multiword Expressions

The number of multiword expressions in a language is unimaginably vast. They could not possibly all go into a dictionary, even one that was unconstrained by the physical limitations of printed books. Nevertheless, some multiword expressions receive entries in dictionaries. These are selected on semantic grounds, not on the basis of frequency, i.e., a dictionary entry is made when the meaning is not recoverable from analysis of the parts. There is no point in putting a frequent collocation into a dictionary if it is perfectly obvious what it means, i.e., if the normal relationship of modifier + noun applies, no matter how frequent the expression may be. The purpose of including a multiword expression in a dictionary is to explain something that needs to be explained. Having said that, it must be acknowledged that there are many multiword expressions with special meanings that are ignored by dictionaries. For example, in English, *forest* and *wood* are synonyms, so it ought to follow that *forest fire* and *wood fire* are synonyms. But they are not. A *forest fire* occurs only in the wild – it is dangerous and out of control; a *wood fire* implies deliberately burning wood in a hearth, under human control, to generate heat. Innumerable similar examples could be cited. Multiword expressions remain a challenge for lexicography. Can a lexicographical project correct the reductionist expectations that would equate *wood fire* with *forest fire*, and if so, how can it be done?

Names in Dictionaries

The traditional criterion for distinguishing names from words is not entirely satisfactory. Common sense suggests that the name 'Samuel Courtauld' denotes a single individual. But in fact there are (or have been) several Samuel Courtaulds in the history of the world, only one of whom founded the *Courtauld Institute of Art* in London. Is *Courtauld* a word of English?

And then what about all the other Samuel Courtaulds? The term *Courtauld* has no particular semantic function; instead, it has a series of denotations, separately picking out all the individuals who bear and bore this surname. Is *Courtauld* a word of English? It is undeniably a type in a corpus. And then, what about the names of all the billions of other people, past and present, in the rest of the world, whether English-speaking or not? There is no difficulty in regarding them as types, because a type is just a processing notion, without reference to meaning. But it would be absurd to call them 'words of English' or put them in a dictionary. However, lexicons for computer use are a different matter. Some of these lexicons contain very large lists of conventional names as an aid to 'named entity recognition.'

Some writers consider that the lexicon is a "cultural system of reference," a criterion that would justify including in a dictionary names that have collective cultural reference, such as *London, Washington, Shakespeare,* and *Courtauld*. Many larger dictionaries such as the *American Heritage dictionary* and the *New Oxford dictionary of English* (NODE) include names that are part of the cultural reference system. Other dictionaries do not, with occasionally bizarre results, for example when *Jesus* gets an entry as an oath (a general word of the language), but not as the name of the founder of the Christian religion. In dictionaries that make this distinction, *English* gets in (presumably, it is a word), but *England* does not (it is a name).

Names of products raise other problems. The term *Mars Bar* is generally considered a name rather than a word, but why? It clearly denotes a class of entities, has a plural inflection, and behaves in other respects like an ordinary English count noun. Yet it is neglected by dictionaries. This may be regarded as a triumph for common sense but not for systematicity. As a type (or rather, a collocation of two types), *Mars Bar* qualifies for entry in large electronic lexicons for natural language processing, since one cannot process English effectively by computer without being able to process *Mars Bar*. And for many applications, knowing that a Mars Bar is candy and not a steel girder is important knowledge, of just the kind that needs to be encapsulated in a computational lexicon.

Bilingual dictionaries, too, include names, but typically only place names for which different language equivalents exist, for example German *München*/ English *Munich*. There is, however, an increasing

fashion in the modern world to use the local form of place names, so that, for example, *Leghorn* (the former English name for *Livorno*) or *Ratisbon* (*Regensburg*) must be labeled as archaic if they are included in a dictionary at all.

Foreign Borrowings

Languages and cultures borrow from one another. For example, speakers and writers freely use French, German, Italian, Spanish, and other expressions in an English-speaking context. The converse is even more true: English is the source of very many foreign borrowings in all the languages of the world. This raises problems for the inventorist.

Is *tete-a-tete* an English word? There are at least three uses of it as a perfectly normal word of English in the British National Corpus. The French form (*tête-à-tête*) is, of course, spelled with accents, but in English it can equally well be written without accents. Many similar examples could be given.

Expletives

Are the English expletives *er, um, oh, unh-huh, phwoah,* etc., words? Should they be in a dictionary? (The same question applies to expletives in any language.) They occur as types in careful transcriptions of spoken English. To that extent, they may be regarded as words, and indeed, nowadays they often make an appearance in dictionaries.

Technical Terminology

Are the coinages of chemists words of English, e.g., *2,3,7,8-tetrachlorodibenzoparadioxin*? Most dictionaries take the view that highly artificial domain-specific terminology of this kind should be classified quite separately from the general vocabulary. Such terms are not words at all, it is said – no more than are the symbols used by logicians and mathematicians.

The problem of terminology is not restricted to the sciences. Sports, too, for example, have an increasingly rich and rarefied range of domain-specific terms. To take an example from cricket: should *silly mid-off* be classified as a 'word'? It makes perfectly good sense in a cricketing context, but is not part of general English. The term has a space in it, which in English normally counts as a boundary between types, but as we have already seen, this is not an infallible guide to identification of word types for a dictionary. Some tokenizers treat the hyphen, too, as a boundary between types, which would make this expression three types. There is no sense (except etymologically) in which it counts as a head noun (*mid-off)* modified by the adjective *silly*. Such an analysis would be a further example of misplaced syntactic reductionism.

Many other examples could be given of the difficulties of processing the evidence of words in text to produce the abstraction that is a dictionary headword list. The fact that there are traditional solutions to such problems, many of them unchallenged, should not blind us to their existence. In this age of computational text processing, lexicographers may need to revisit their most basic assumptions about what a word is.

The Internal Structure of Dictionary Entries

Once the evidence has been collected and organized into alphabetical order or some other order, the lexicographer must start writing the entry. In practice, especially in dictionaries involving large teams of lexicographers, the two components of the work go hand in hand. There is considerable overlap. Collection of evidence – especially evidence for new and 'trendy' words beloved of publishers' marketing departments – normally continues until the last possible moment before publication.

Dictionaries are among the most highly structured texts known to humans. They consist of hundreds of thousands of little bits of information, carefully pieced together in an ordered pattern. An entry in a large dictionary typically contains at least the following information types: orthography, pronunciation, grammar, definitions, examples of its use, phraseology, prescriptive comments and usage notes, and a word history.

Orthography

The single most common use of practical dictionaries in English and other languages is to check spelling. English spelling, though eccentric, is settled (with very few exceptions) and inflections are few, so it would be easy for an English lexicographer to overlook the amount of work that goes into deciding on orthography in other languages, for example, Irish Gaelic, for which a complete new orthography was developed for the language in the 20th century, or German, which undergoes periodic bouts of spelling reform. In non-European languages it is sometimes necessary for a lexicographer to make a principled decision about which dialect should be represented as the lexicographical standard or how many variants should be shown. Great historical dictionaries, such

as the OED, typically list the variant spellings that were in use at different periods in history.

The orthography of inflected forms, too, must be represented. Again, English is at an advantage in that it has comparatively few inflections and those that exist are mostly regular. It is no great burden to list the inflected forms of the few strong verbs that exist and other irregular forms. In German, plurals of all countable nouns and inflected forms of strong verbs must be indicated. In highly inflected languages such as Czech, inflections can generally be represented by reference to tables of declensions and conjugations. However, there are often variants and irregularities, all of which must be represented somehow. The lexicographer must also decide systematically which inflected forms must be represented and which can safely be ignored (either because they are regular or because they are rare or obsolete).

Pronunciation

Many dictionaries offer a guide to pronunciation of the headwords (and in some languages also of inflected forms), especially dictionaries of languages such as English, where the relationship between orthography and phonetics is not entirely regular. If it is decided to represent the pronunciation of words independently of their orthography, there are two major questions that the lexicographer must address: which accent to represent, and which transcription system to use. A question that is of great importance but that does not arise in relation to dictionaries is whether the representation should be of the word as it is normally pronounced in coherent speech or whether it should be a 'reading-list pronunciation.' Dictionaries deal with words in isolation, so they can only offer a reading-list pronunciation, which is a kind of abstract idealization.

Electronic dictionaries can, in principle, offer a choice between a written transcription and an audio representation. As long ago as 1969, *Webster's New World dictionary* pioneered the practice of accompanying the printed text of a dictionary with an audio representation of the pronunciation of words. Other dictionary publishers have followed suit from time to time, and now several have taken advantage of the potential of electronic technology in this respect. The audio representation may be taken from a list of words read by a human being, a text-to-speech synthesis, or both. In either case, a decision has to be made about which accent should be represented. As electronic dictionaries in hypertext form become better established, it may be expected that more detailed lexicographical attention can be given to the pronunciation of words in different accents.

Which accent to represent? This is a tricky question. The dictionary must either choose one accent as being standard and representative, or it must attempt a representation of several different standards, which can sometimes be done by using symbols that have an 'archetypal' value, i.e., each symbol can have a different value for each different accent. Of course, this only works insofar as the relationship between accents is regular; otherwise, alternative transcriptions must be offered.

Even in languages where one accent is generally recognized as standard, problems can arise. For British English, the representation of pronunciation is usually in a standard accent, which Daniel Jones called 'received pronunciation' (RP), defining it in the 1926 edition of his *English pronouncing dictionary* as the accent of English "which is the everyday speech of families of Southern English persons whose menfolk have been educated at the great public boarding schools." Thus, it is not only a regional accent but also a class accent. At that time, and for many years thereafter, English learners and many non-RP speakers aimed at RP in formal contexts, with varying degrees of success. In the intervening 80 years, however, since Jones wrote those words, RP itself has changed, although guides to English pronunciation, by and large, have not. In the *Oxford dictionary of English pronunciation* (ODEP, 2001), Clive Upton commented that the accent represented by Jones's model had become "the possession of a small minority restricted in terms of age, class, and region." The ODEP offered "a younger, unmarked RP." The differences are mainly in terms of vowel quality. The ODEP also offered guidance on American pronunciation. Upton's co-author, William Kretzschmar, commented that "English in the United States has no obvious standard spoken model" but that there was a "trend among educated speakers, especially those of the younger generation, toward limitation of the use of marked regional features while speaking in formal settings." As far as Australian English is concerned, the *Macquarie dictionary* offers a transcription of English words in a standard Australian accent, and several other dictionaries of national varieties of English likewise offer a representation of a local standard accent. Languages that have a rich variety of dialect pronunciations, no one of which can be regarded as standard, tend to avoid giving guidance in dictionaries on pronunciation of words, since to do so risks raising more problems than it solves.

Which transcription system to use? The obvious scholarly choice for many dictionaries is the International Phonetic Alphabet (IPA) (*see* **International Phonetic Association** and **Phonetic Transcription: Analysis**). This, however, has its disadvantages. The symbols of IPA have an absolute value, so that even a broad transcription is accent-specific. Moreover, since accents change over time, an IPA transcription becomes out of date more rapidly than the alternative (a spelling-rewrite system). Perhaps these are among the reasons why almost all American English dictionaries prefer a spelling-rewrite system (borrowing only the schwa symbol, /ə/, from IPA).

Grammar

The presentation of grammar in dictionaries (as distinct from part-of-speech labels) is, for English at least, a controversial subject. There are many things that must be included – e.g., that the verb *put* requires not only a direct object, but also an adverbial of place – but the public are said to be resistant to too much grammar. Inclusion of detailed grammatical information about word usage is not a popular selling point. There are two ways in which dictionaries deal with this problem. One, adopted by NODE in 1998, is to make a stringently considered selection of necessary grammatical statements and to present them in unabbreviated English words and phrases such as "with adverbial of place." The second is to devise a notational system that refers to an appendix on syntactic patterns of word use. The first edition of *Longmans' dictionary of contemporary English* (LDOCE, 1978) devised such a system. It is very detailed and has the merit of taking up very little space, but it is not self-explanatory and only the most hardened seekers of grammatical truth seek out the appendixes and unpack all the grammatical information relevant to each word.

Definitions

In the English-speaking world, definition writing is often seen as the central part of the lexicographical task. The project leader of a large lexicographic project keeps a set of compilers' instructions and tries to ensure that all members of the team are writing in roughly the same style and in a consistent way. Some of the principal issues in definition writing are discussed elsewhere in this encyclopedia (*see* **Definition**). A dictionary that sets out to record the whole vocabulary of a language must devise separate styles for explaining function words and for discourse organizers, sentence adverbs, and other 'pragmaticky' expressions, as well as many kinds of nonlexical information, such as the New Latin terms for species of plants and animals or the formulae of chemical compounds.

Examples of Words in Use

For many European dictionaries, the selection of examples of usage is seen as a central activity. By contrast, exemplifying usage is a neglected aspect of some older one-volume English dictionaries.

In scholarly historical dictionaries such as OED, examples of words in use are cited from literature, with date, author, and other bibliographical details. It is this, and not only the size of the word list itself or the richness of definition, that contributes principally to the multivolume bulk of such dictionaries.

One-volume dictionaries make a selection of examples, showing how different senses of words are ordinarily used. Nowadays, with the easy availability of machine-readable corpus evidence, such examples are usually chosen from authentic texts rather than invented by the lexicographer, but still careful selection is needed to avoid the risk of giving examples that are taken from eccentric or high-flown literary usage. Despite the efforts of linguists in recent decades, selectional preferences are still not well understood (let alone well described), so prudence dictates that the lexicographer should use authentic examples rather than invented ones. Many learners' dictionaries and textbooks of the 1970s contain examples of usage concocted by the writers which (presumably unconsciously) violate selectional preferences. On the other hand, authenticity alone is not enough: authentic texts are full of colorful and eccentric language. The lexicographer who wishes to help a user encode the language is under an obligation to choose examples that show words in their most central and typical usage. One might almost say that such examples should be chosen for their dullness.

Phraseology

Brief mention must also be made of phraseology in dictionaries. Entire dictionaries are devoted to idioms and idiomatic expressions (*see* **Idiom Dictionaries**). Common idioms are also explained in general dictionaries, typically at the end of the entry for one of the key words in the idiom. Bilingual dictionaries give a great deal of information about phraseological equivalents in different languages, seeking to help the user overcome the problem that many expressions cannot be translated word for word.

Large monolingual dictionaries of some European languages, such as German and modern Greek, devote more space to listing common phraseology, showing how words are used, than to explanations of meaning.

Prescriptive Comments and Usage Notes

As stated above, users often expect guidance from a dictionary on matters of 'correct' and 'incorrect' usage, paying no heed to the lexicographers' protestations that their task is merely descriptive. Some prescriptive works do exist, for example, H. W. Fowler's *Modern English usage* (1926), revised and updated by R. W. Burchfield in 1983, which is much admired for its robust and sometimes humorous advice on various aspects of English style. Perennially popular, too, are more basic practical works, such as the *Oxford guide to style* (2002) (a successor to *Hart's rules for compositors and readers at the Oxford University Press*) and Judith Butcher's *Copy-editing: the Cambridge handbook for editors, authors, and publishers,* which concern themselves with such matters as hyphenation, punctuation, italicization of foreign words and phrases, and consistency of spelling.

Large practical dictionaries deal with the problem of the demands of ordinary users for prescriptive instructions about word usage either by ignoring them or by including a commentary on controversial issues, such as the use (in English) of split infinitives, competing pairs such as *disinterested* versus *uninterested*, and the use of taboo words. These comments may be no more substantial than register labels such as 'slang' or 'taboo' (*see* **Register: Dictionaries**), or they may be fairly substantial essays. NODE made a concerted attempt in its longer usage notes to bring corpus evidence to bear, comparing what writers actually write with what the pundits say they ought to write. The *American Heritage dictionary* contains usage notes, edited by Geoffrey Nunberg, in which the opinions of a panel of pundits (173 of them in the 1992 edition) are summarized on different issues, e.g., whether it is correct to use *impact* as a verb:

> "... 84 percent of the Usage Panel disapproves of the construction *to impact on*, as in the phrase *social pathologies, common in the inner city, that impact on such a community*; and fully 95 percent disapproves of the use of *impact* as a transitive verb in the sentence *Companies have used disposable techniques that have a potential for impacting our health*..."

Word Histories

Bilingual dictionaries and dictionaries for foreign learners do not normally say anything about etymologies, word histories, or obsolete senses. However, most larger dictionaries for native speakers see it as an essential part of the lexicographical task to explain not only the meaning but also the history and semantic development of each word, or at least of the main root words. The meaning of a word can often be illuminated by knowledge of its etymology, for example, that the English verb *concatenate* is ultimately derived from the Latin noun *catena* 'chain' or that the modern German verb *leisten* (a word for which there is no English equivalent, the translation varying according to context: *Gehorsam leisten* is 'to obey,' *Hilfe leisten* is 'to help,' *Arbeit leisten* is 'to do work,' *ein Eid leisten* is 'to swear an oath') is derived from an ancient Germanic verb meaning 'to follow in the footsteps (of a feudal superior).' Etymologies tell a culturally unifying story about the interactions between languages and cultures. In a hybrid language such as English, even something as simple as an indication that a word is of Germanic or Latin origin, as the case may be, is illuminating information included in many small dictionaries, including dictionaries for schoolchildren.

A dictionary on historical principles places the etymologies first in the explanations, immediately following the headword and pronunciation. Etymologies in great scholarly dictionaries such as the third edition of OED, now in progress, can be quite extensive and amount almost to scholarly articles in their own right.

Practical dictionaries on synchronic principles take a slightly different view of word histories. First, there is more emphasis on semantic development; second, there is less emphasis on morphological development; and third, information about important obsolete senses (which in a dictionary on historical principles usually appears first among the definitions) may be placed in the etymology or 'word history.'

A primary concern of dictionaries on historical principles is with dating. Many practical synchronic dictionaries of English give information about the earliest date at which a word was recorded in the language. Since this can rarely be done with absolute precision, the date is generally given in terms of a spread of dates; *Collins* gives the century in which the word was first recorded, relying largely on the historical evidence of OED; the *Random House dictionary of the English language* (2nd edn., 1987) generally indicates the decade (or some other spread of years) in which the word was first recorded and seems to be similarly indebted to OED.

The Future of Lexicography

The Challenge of Corpus Evidence

The inventory of the words of well-known languages like English, Spanish, French, Italian, Russian, and German is well established (within certain conventional limits). Increasingly sophisticated efforts have been devoted to recording the words of these

languages for over three centuries. They are widely spoken and have a vast literature, and the main task of the lexicographer has traditionally been to record new words, new phrases, and new senses of words as they develop. In other words, the task of the lexicographer is (or was) to maintain an existing dictionary, adding to the existing text new words and new senses as they arise. This is still the case in the United States. However, this comfortable conservative notion has been shaken somewhat since the mid–1980s with the development of large machine-readable corpora of languages (*see* **Corpus Linguistics**). Fashionable linguistic theories of the 1970s and 1980s required a language to consist of a 'lexicon' (a fixed inventory of lexical items) and a 'grammar' (a fixed set of rules), but corpus analysis has shown that the lexicon consists not only of a large number of regular words, but also of an unbounded number of words that have occurred only once, even in very large corpora, and that may never occur again – words such as *giraffishness,* which occurred once in an Associated Press news item for 1988 and has never been seen since – while even quite common words are sometimes used in a way that is not satisfactorily accounted for by received grammatical rules and 'selectional restrictions' (a term that must be contrasted with 'selectional preferences'). In other words, the lexicon itself is dynamic. New words are coined all the time, both by recombination of existing morphemes and by productive use of the phonological system of the language. Moreover, the meaning of a word (in particular, the everyday words of a language, as opposed to technical terms such as *mammal*, which have scientifically stipulated definitions) is to a large extent dependent on the context in which it is used. For example, the verb *treat* denotes attitude or behavior if it is used with an adverbial of manner, but is more likely to denote a medical procedure if there is no adverbial. The sentence "I hazarded various Stuartesque destinations like Florida, Bali, Crete, and Western Turkey" (British National Corpus) can only be explained as a dynamic exploitation of a normal use of the verb *hazard*, involving the use of ellipsis ("I hazarded *a guess at* various Stuartesque destinations . . ."). In addition, the word *Stuartesque* is not regular in English; it must be explained in terms of the personal name *Stuart* and the bound morpheme *–esque*. Corpora offer many such challenges to lexicographers; on the other hand, they can equally well be used as a pool in which to fish for examples that support existing hypotheses.

Monolingual lexicography is only just beginning to come to terms with the challenge of corpus evidence. English dictionaries that have devised corpus-driven procedures for the description of the lexicon from the outset are *Cobuild* (1st edn., 1987), the *Cambridge international dictionary of English* (1995), NODE (1998), and the *Macmillan English dictionary* (2002). Older established dictionaries, including OALD (the *Oxford Advanced Learner's dictionary*) and LDOCE, have revised their entries systematically in the light of corpus evidence but have not radically revised their theoretical foundations. All except NODE are dictionaries for foreign learners of English. There are other dictionaries whose publishers claim or imply a corpus connection, even though the text remains virtually unchanged from earlier editions, compiled before electronic corpora were available. In other languages, the situation is similar. For example, the *Duden* dictionaries contain some recent updates of entries that appear to be beholden to the evidence of the corpus of the Institut für deutsche Sprache, but a systematic new corpus-based analysis of the German lexicon has still to appear. Ironically, it is dictionaries of languages with smaller populations, such as Irish Gaelic and Korean, that seem to be taking the lead in exploiting the new opportunities afforded by corpora.

Online Lexical Resources

The Internet is tailor-made for lexicographical projects. The constraints of the printed page (two-dimensional, limited space, printed in expensive multivolume format, etc.) do not apply, although this opens the door to possible faults, such as prolixity and excessive ingenuity.

At the present time, however, these faults are not a major preoccupation. Online dictionaries have not yet taken full advantage in any language of the potential of computer technology. This may in part be due to the great expense of setting up something such as a hypertext dictionary for a whole language and the lack of a clear business model. The economics of dictionary publishing in book form, though sometimes nerve-wracking, have the merit of being well understood. The economics of online publishing are as yet somewhat unstable: they have not yet had a chance to stand the test of time. A well-known and universally admired traditional project such as the OED succeeded in attracting online subscriptions from major institutional libraries to help finance the preparation of its third edition, but such funding is less likely to be forthcoming for a more radical, innovative project. The situation is further complicated by the fact that the funding agencies that can normally be expected to fund radical and innovative research projects are shy of infrastructure projects such as

dictionaries and even more reluctant to fund new editions of existing resources.

Major academic research projects on the lexicon in recent years, such as WordNet and FrameNet, point the way to what is possible, but they are only a beginning. A full multimedia account of the lexicon of any language in hypertext form is at present no more than a pipe dream.

Information Sources, Conferences, and Associations

The leading journals for lexicography are *The International Journal of Lexicography,* published quarterly, and *Dictionaries: The Journal of the Dictionary Society of North America,* published annually. The former contains articles not only in English but also in French and German. It takes a global view of lexicography, with articles on dictionaries of all languages, although the chief focus is, not surprisingly, on dictionaries of the major European languages – monolingual and bilingual, synchronic and diachronic, pedagogical and encyclopedic.

Conferences and workshops on lexicography are regularly organized by lexicography associations in every continent in the world. Chief among these are Euralex (biennial conferences since 1983 plus other workshops), Australex (biennial conferences since 1990), Afrilex (annual conferences since 1996 plus other workshops; *see* **African Lexicography**), Asialex (biennial conferences since 1997), and the Dictionary Society of North America (annual conferences since 1975). A regular conference on computational lexicography, Complex, has been hosted each year since 1992 by the Linguistics Institute of the Hungarian Academy of Sciences in Budapest.

A seminal conference was held as long ago as June 1972 under the auspices of the New York Academy of Sciences, the proceedings of which appeared in 1973, edited by McDavid and Duckert and including papers by Bolinger, Zgusta, McIntosh, Quirk, Burchfield, Lakoff, McCawley, Malkiel, Quine, Urdang, and others. Although the title of the collection is *Lexicography in English,* some of the papers touch on issues that are of general relevance to lexicography in all languages.

Reliable and informative discussions of lexicography as a discipline include those by Landau (2001), Jackson (2002), and Svensen (1993), and the papers collected by Hartmann (2003). An important reference work is a massive three-volume collection of essays on all major aspects of lexicography, edited by Hausmann *et al.* (1989–1991). A survey of the terminology of the field is Hartmann and James (1998). Other important contributions were made by Zgusta (1971, 1988).

Lexicology

A Cowie, University of Leeds, Leeds, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction: The Scope of Lexicology

Lexicology is 'the study of the *lexicon* or *lexis* (specified as the vocabulary or total stock of words of a language)' (Lipka, 1992: 1). For English-speaking linguists familiar with teaching and research in the subject in France and Germany, there is a 'classical' as well as an 'evolved' view of what is meant by the term. The classical view is brought home by examining the contents of standard textbooks written in Germany for university students of English. The title of one of the best known is *Englische Lexikologie*, with the subtitle *Einführung in Wordbildung und lexikalische Semantik* ('Introduction to word formation and lexical semantics'), which highlights its central elements (Hansen *et al*., 1992). And the handbook does indeed deal in successive major sections with word formation (broken down into 'compounding' 'derivation' [including 'zero-derivation'], 'reduplication' and 'blends') and lexical semantics, in which one major subsection deals with 'relations within words' (including 'homonymy' and 'polysemy,' and 'metonymy' and 'metaphor') and another with 'paradigmatic semantic relations between words' (including 'antonymy' and 'hyponymy'), which are in Britain often referred to as sense relations (Lyons, 1977). Matching for the most part this view of what a lexicology textbook should contain is Tournier's broad, masterly work (Tournier, 1985), with major chapters devoted to derivation, compounding, and conversion (and thus to word formation), and also to *metasémie* (or meaning change), which features several of the themes that, in the German work, are subsumed under lexical semantics. There are of course differences of detail between the two works.

Interestingly, there are no parallels in Britain for textbooks dealing with the lexicon in quite the way I have just described. Further, the term 'lexicology' has not until comparatively recently been used in linguistics textbooks published in Britain or defined in many 'desk-sized' dictionaries (not, for example, in the *Concise Oxford dictionary* until the eighth edition of 1990). Moreover, in British practice the two main topics that are given prominence by both Tournier and Hansen *et al*. are hived off into separate volumes: word formation to Bauer (1983), lexical semantics to Cruse (1986).

However, in many areas where British lexicologists work in close collaboration with colleagues from various European countries, the term of choice is almost universally 'lexicology' (rather than 'lexical semantics'). In the proceedings of recent congresses of the European Association for Lexicography, for instance, we find section headings such as 'Computational Lexicography and Lexicology' and 'Reports on Lexicographical and Lexicological Projects' where the coupling of related areas of professional concern is underpinned by the formal relatedness of the terms (Braasch and Povlsen, 2002a). There are of course other linkages of form and meaning that help to explain a growing preference. In addition to the connection to lexicography, lexicology is related in form to a number of terms (phonology, morphology, phraseology) denoting other levels of linguistic analysis. Then again, the term has been broader in its application than lexical semantics, having, with

Introduction: The Scope of Lexicology

Lexicology is 'the study of the *lexicon* or *lexis* (specified as the vocabulary or total stock of words of a language)' (Lipka, 1992: 1). For English-speaking linguists familiar with teaching and research in the subject in France and Germany, there is a 'classical' as well as an 'evolved' view of what is meant by the term. The classical view is brought home by examining the contents of standard textbooks written in Germany for university students of English. The title of one of the best known is *Englische Lexikologie*, with the subtitle *Einführung in Wordbildung und lexikalische Semantik* ('Introduction to word formation and lexical semantics'), which highlights its central elements (Hansen *et al*., 1992). And the handbook does indeed deal in successive major sections with word formation (broken down into 'compounding' 'derivation' [including 'zero-derivation'], 'reduplication' and 'blends') and lexical semantics, in which one major subsection deals with 'relations within words' (including 'homonymy' and 'polysemy,' and 'metonymy' and 'metaphor') and another with 'paradigmatic semantic relations between words' (including 'antonymy' and 'hyponymy'), which are in Britain often referred to as sense relations (Lyons, 1977). Matching for the most part this view of what a lexicology textbook should contain is Tournier's broad, masterly work (Tournier, 1985), with major chapters devoted to derivation, compounding, and conversion (and thus to word formation), and also to *metasémie* (or meaning change), which features several of the themes that, in the German work, are subsumed under lexical semantics. There are of course differences of detail between the two works.

Interestingly, there are no parallels in Britain for textbooks dealing with the lexicon in quite the way I have just described. Further, the term 'lexicology' has not until comparatively recently been used in linguistics textbooks published in Britain or defined in many 'desk-sized' dictionaries (not, for example, in the *Concise Oxford dictionary* until the eighth edition of 1990). Moreover, in British practice the two main topics that are given prominence by both Tournier and Hansen *et al*. are hived off into separate volumes: word formation to Bauer (1983), lexical semantics to Cruse (1986).

However, in many areas where British lexicologists work in close collaboration with colleagues from various European countries, the term of choice is almost universally 'lexicology' (rather than 'lexical semantics'). In the proceedings of recent congresses of the European Association for Lexicography, for instance, we find section headings such as 'Computational Lexicography and Lexicology' and 'Reports on Lexicographical and Lexicological Projects' where the coupling of related areas of professional concern is underpinned by the formal relatedness of the terms (Braasch and Povlsen, 2002a). There are of course other linkages of form and meaning that help to explain a growing preference. In addition to the connection to lexicography, lexicology is related in form to a number of terms (phonology, morphology, phraseology) denoting other levels of linguistic analysis. Then again, the term has been broader in its application than lexical semantics, having, with

suitable modification, referred to diachronic lexical studies (hence 'historical lexicology'; cf. Ullmann, 1957: 39) and contrastive lexical studies (hence 'contrastive lexicology'; cf. Van Roey, 1990).

A number of major topics from outside the traditional core are currently subsumed under the heading 'lexicology.' This brings me to my reference earlier to an 'evolved' view. One cannot avoid noticing a greater breadth of coverage in the latest edition of what is probably the best-known German textbook (Lipka, 2002). Not only do we find the topics treated that we have come to take for granted in such a text – homonymy vs. polysemy, lexical fields and hierarchies, and lexical rules and semantic processes – but there are other themes that fall outside its traditional limits, including corpus linguistics and cognitive linguistics – both to be considered below – while there is extensive discussion in Lipka's Introduction of 'the expanding field.'

This article attempts to reflect this greater diversity of themes. Polysemy and homonymy in the first section belong to the traditional core of the subject (Cowie, 1994). The second section is devoted to cognitive approaches to the analysis of metaphor based on the work of Lakoff and to a project in the 'syntagmatics of metaphor' that draws extensively on very large text corpora. The final section is taken up with an approach to lexical description – 'frame semantics' – that brings together syntactic and semantic levels of description in a rigorous and systematic way.

Polysemy and Homonymy

Though polysemy and homonymy are long-established concepts in lexicology, they continue to excite discussion among linguists (e.g., Cowie, 2001; Ravin and Leacock, 2000). The concepts themselves and the relationship between them are of crucial importance to lexicographers, since they require sound criteria to determine whether different occurrences of a given word represent different senses and, if different, how different. As we shall see, approaches to meeting this need which lay emphasis on the contrastive lexical environments of such occurrences (their differing collocability) have much to offer, especially as evidence is now available from immensely large text corpora (Hanks, 2004a).

Polysemy and homonymy can be defined in general terms as follows. When a given word form (i.e., in the written language, any sequence of letters bounded on either side by a space) realizes two or more related though separate meanings of the same lexical item, we have polysemy. (Compare: $thick_a$ 'having density'; $thick_b$ 'with a large number of units close together'.) When, however, the word form functions as the realization in speech or writing of more than one lexical item, we have homonymy. (Compare: $meal_1$ 'flour'; $meal_2$ 'repast'.)

Though the phenomena are often linked, polysemy is more widespread than homonymy, and of much greater significance. Homonymy may come about through the chance convergence of two distinct forms ($meal_1$ coming from Old English *melo* and $meal_2$ from Old English *mæl*). Polysemy, however, is typically the result of lexical creativity and is crucial for the functioning of a language as an efficient semiotic system (Lyons, 1977: 567; Lipka, 1992: 136). It is also true that the distinction between homonymy and polysemy is not the simple dichotomy that is sometimes believed, but is in the nature of a scale or cline. This becomes unarguable once it is accepted that every case of polysemy involves relatedness as well as difference of meaning (Cowie, 2001). As recent studies have shown, however, there is still a tendency to emphasize the latter at the expense of the former (Ravin and Leacock, 2000b).

Three major issues need to be addressed in treating this opposition. First, we need to take account of the phenomenon of 'modulation,' or 'contextual variation,' of a single sense (Cruse, 1986). It is sometimes claimed, rather loosely, that the sense of a (polysemous) item is determined by its context. Such claims, however, fail to distinguish between the unrestricted, and often ephemeral, 'shaping' of a word by its context and the more familiar variation attributable to context, which is the activation by different contexts of existing and possibly well-established senses of polysemous words. An example of a meaning difference attributable to modulation – but where there is only one sense – appears below (cf. Moon, 1987):

> He took the cigarette out of his mouth [the opening].
> She had a wide and smiling mouth [the lips].

The second issue that needs to be considered is whether, when attempting to identify polysemy or homonymy, we need to take account of more than one criterion (for checklists, see Lipka, 1986; Cowie, 2001). A further, related, issue is whether we should give prominence to semantic rather than formal criteria. To begin with the question of multiple criteria, it seems vital, given the nature of polysemy as a scalar phenomenon, to refer in each case to two or more criteria. If one takes two or more occurrences of the same word form, and finds that they have similar distributions at a number of descriptive levels – syntactic, morphological, collocational – then the assumption is that they will be close in meaning and

at the most remote point from homonymy. Consider, with this in mind, the following senses of the noun *tour*, noting especially the possible conversion of the noun – in one or more senses – to a verb, and any other characteristic derivatives (Cowie, 2001: 46).

a. tour (holidays)	tour (v), tourist, tourism
b. tour (visit, inspection)	tour (v)
c. tour (military)	tour (v)
d. tour (artistic)	tour (v)
e. tour (sporting)	tour (v), tourist

We can see that in terms of conversion ('zero derivation') the various senses are alike, while as regards derivation proper, only the first stands out from the others (note also the compounds *package tour* and *tour operator*). By contrast, near-homonymy will be indicated when, for a given set of criteria, one finds wide distributional differences. Such is the case with three senses of the adjective *sheer*, where the synonyms are sharply distinct and the pattern with *sheerness* is only fully acceptable in the first sense:

sheer_a ('very steep')	= perpendicular (cf. the sheerness of the rock face)
sheer_b ('absolute')	= unmitigated (cf. *the sheerness of his folly)
sheer_c ('so fine as to be transparent')	= diaphanous (cf. ?the sheerness of her tights)

As for giving priority to semantic criteria, we should take account of the view of Cruse (1986, 2000) on how polysemy should be defined, while noting its limitations. Cruse favors semantic (or 'direct' tests), which he describes as more successful and reliable for diagnostic purposes. One such test depends on the fact that separate senses of an item cannot be brought into play in the same sentence without oddness. Consider for example this sentence, where activating two senses of *expired* at the same time gives rise to zeugma: ?*John and his driving license expired last Tuesday.* Nevertheless, the meanings of different lexical items differ quite widely as to the degree of oddness that is revealed when they are brought into play. In this sentence, for instance, where senses of *tour* are (again) involved, no oddness is involved: *The England cricketers and the Royal Ballet were both touring South Africa*. Yet this is only to be expected if the senses of a polysemous word are – in differing degrees – related as well as separate. More positively, one could conclude that, while no better in this respect than grammatical tests, semantic tests **do** provide evidence of the scalar nature of polysemy.

Metaphor and the Differentiation of Meanings

As many entries in ordinary dictionaries confirm, metaphor is one of the commonest means by which new meanings develop from existing senses. The prevalence of metaphor more generally, as an integral part of the structure of the lexicon, has been highlighted in the field of cognitive semantics and in particular in the work of Lakoff and Johnson (1980) and Lakoff (1987). Lakoff and Johnson argued that we can point to a number of very general concepts whose metaphorical structuring is reflected in the phrasal lexicon of the language (1980: 52), and they gave weight to their hypothesis by showing that particular metaphors, such as 'ideas are cutting instruments,' are manifested by a cluster of specific phrases:

> That's an *incisive* idea. That *cuts right to the heart of* the matter . . . He has a *razor* wit. He had a *keen* mind. (Lakoff and Johnson, 1980: 48).

It is worth noting that elsewhere the authors pointed out that a particular set of phrases 'structured by a single metaphorical concept' ('life is a gambling game') are 'phrasal lexical items' (or, to use a common equivalent, multiword units). Such examples reinforce the point made earlier, that metaphorical concepts are characteristically realized by expressions from the **phrasal** lexicon (Lakoff and Johnson, 1980: 51).

The link between Lakoff and Johnson's hypothesis and phraseology has been seized on by a number of linguists. Referring to a collocational database enriched by having had 'lexical functions' assigned to each of the 70 000 pairs of collocations it contains, Fontenelle noticed that other metaphors are commonly used in the language (Fontenelle, 1994: 275; and for lexical functions cf. Mel'chuk and Zholkovsky, 1984; Fontenelle, 1997). He considered the following examples from the database (introduced by the function 'Mult,' expressing 'a group or set of something'):

Mult (arrow)	=	cloud, rain, shower, storm
Mult (bullet)	=	rain
Mult (missile)	=	storm
Mult (stone)	=	shower

Arrow, *bullet* and so on are projectiles aimed at a target. But as Fontenelle explained, these terms are used in collocation with words pertaining to meteorological phenomena, enabling us to posit the existence of the metaphor 'a projectile is a meteorological phenomenon.'

The approach to the definition of metaphor followed by Patrick Hanks must be viewed as part of his much broader theory of norms and exploitations, developed as a response to the pervasiveness in language use of what he has called "stereotypical syntagmatic patterns" (Hanks, 2004a). What the term points to is repetitive use (abundantly illustrated by Hanks), relative fixity, and preference for the form in question over plausible alternatives (well illustrated by native speakers preferring *a storm of protest* to *a torrent of protest*). Such examples as *a storm of protest* and *a torrent of abuse* represent the 'norm.' As Hanks explains, 'some uses are stereotypical; others exploit stereotypes, typically for rhetorical effect' (2004b: 246), and he goes on to develop the point by suggesting that whereas stereotyped phrases and idioms are 'norms,' innovative adaptations – often based on existing phrases, as in *the vultures are circling* vs. *the lawyers are circling* – are 'exploitations.' Clearly, dead metaphors will figure in the first category and freshly minted metaphors in the second.

The treatment of metaphor provided by Hanks is detailed and often illuminating. It is clear, first, that we must recognize 'degrees' of metaphoricity, in the sense that neither, one, or both of the constituents of a phrase may be metaphorical:

a. The lowest point on the scale is represented by *storms blow*, *storms abate*, where there are arguably two literal elements and 'a reductionist interpretation is appropriate' (Hanks, 2004b: 256).
b. We come next to cases where *storm* is literal but the associated verb is figurative: *storms brew* and *rage*; *storms batter*, *lash*, and *ravage*. Such combinations are so common that 'it is easy to overlook the metaphorical status of the verb' (Hanks, 2004b: 256). It is worth noting, too, that in treatments influenced by 'classical' Russian theory, *storm* would be said to 'shape' the figurative senses of *batter*, *lash*, etc. (cf. Cowie, 1999).
c. In the third type, *storm* is metaphorical, as in *a political storm*, *a storm of protest*.
d. At the final stage we find idioms, such as *a storm in a teacup*.

There is a particularly interesting comment on *storm* (i.e., as a conventional metaphor) as the direct object of a causative verb. The causative may be literal, as witness *cause*, *create* and possibly *raise*. But '*storm* in this sense is found as the direct object of both literal and metaphorical causative verbs' (Hanks, 2004b: 259). In the latter case, we have mixed metaphors: *spark a storm* (*of protest*, etc.), *whip up a storm*. The mixed metaphor effect is perhaps caused by *spark* (say), which acts originally as a collocate of *explosion*, later carrying over the appropriate features to *storm* (for 'oblique' metaphors, see Cowie, 2004).

Finally, and still on the subject of conventional metaphors, Hanks made two observations that only access to extensive data could make possible. In causative *brew up a storm*, *whip up a storm*, etc., the noun is almost certainly metaphorical. In inchoative *a storm is brewing up*, by contrast, the noun could be either. Other contrastive comments are prompted by *a storm of* something, where the final noun is almost always a conventional metaphor and negative: *a storm of protest*, *a storm of criticism*, etc. Less common are positive reactions, such as *a storm of applause*.

Frame Semantics

Considerable interest is currently being shown by lexicologists and specialists in lexicography and natural language processing in frame semantics, an approach to the study of lexical meaning based on work by Charles Fillmore and his associates. A particular strength of the theory is that it brings together syntactic and semantic levels of analysis in a rigorous and systematic way. But of particular significance is the contribution that the theory makes to the analysis of words, and thus to lexicography. As Atkins, Fillmore and Johnson pointed out, experienced lexicographers will use various clues to identify differences in the meaning of a word when examining citations in which it appears. In the case of the verb *argue*, for example, the indicators of difference will include different synonyms (*quarrel* in one case, *reason* in another) and contrastive sets of prepositions: 'in the quarrelling sense, you argue *with* someone, *about* something, while in the reasoning sense you argue *for* or *against* something, or *that* something should be done' (Atkins *et al.*, 2003: 253).

By making implicit use, as here, of various kinds of linguistic information, the practical lexicographer can make considerable progress towards identifying or separating senses. However, if recognized explicitly, the information can lead to deeper understanding. One kind of information has to do with the syntactic contexts in which *argue* occurs; the other concerns the meanings of the prepositions (*with*, *for*, and so on) which function as its complements. Beyond that awareness is the recognition that we need a theory that links the meanings of words very explicitly to the syntactic contexts in which those words are used, and to the semantic properties of those contexts. In frame semantics, this requires a further step, which is to recognize that 'word meanings must be described in

relation to *semantic frames* – schematic representations of the conceptual structures and patterns of beliefs, practices, institutions, images, etc. that provide a foundation for meaningful interaction in a speech community' (Fillmore *et al.*, 2003: 235).

Those working on semantic frames have an associated computational lexicography project, FrameNet, which extracts information about the related semantic and syntactic properties of English words from large text corpora, and analyzes the meanings of words "by directly appealing to the frames that underlie their meanings and studying the syntactic properties of words by asking how their semantic properties are given syntactic form" (Fillmore *et al.*, 2003: 235). In this way are the grammatical and semantic features of *argue*, presented informally earlier on, given more rigorous and systematic shape.

The notion of valence – at the grammatical level, the requirement that a word combines with particular phrases in a sentence – plays an important part in the theory. However, in FrameNet, information about valence must be stated in semantic as well as syntactic terms. That is, the semantic roles that syntactic elements such as subject or object play with reference to the meaning of the word must be fully accounted for.

In FrameNet, 'the semantic valence properties of a word are expressed in terms of the kinds of entities that can participate in frames of the kind evoked by the word' (Fillmore *et al.*, 2003: 237). These roles are called frame elements (FEs). FEs must be taken to include not only the human participants – aggressors, victims, etc. – but conditions and objects relevant to the central concepts of the frame. In the semantics of the key term *risk* – the subject of a detailed study by Fillmore and Atkins (1992) – such elements include uncertainty about the future (the frame element 'chance') and a potential unwelcome development (the frame element 'harm'). According to the study, these two FEs alone make up the core of our understanding of several other items within the field, including *peril*, *danger*, *venture*, and *hazard*.

Semantic frame theory offers a number of opportunities to lexicologists and lexicographers in treating the vocabulary of risk and other semantic domains (Cowie, 2002). First is the fact that the model brings together frame elements and syntactic functions, so that the one-to-two (or one-to-many) relations that often hold between FEs and lexicosyntactic structures are clearly demonstrated.

To illustrate this point, we can see, just below, that the frame element 'aggressor' is common to both examples. This perception leads us to bring together – as semantically related – two contrasting structures incorporating the noun *threat*, in which 'aggressor' is realized first as a grammatical subject and second as a prepositional phrase introduced by *from* (Cowie, 2002: 327):

1. AGGRESSOR {the dolphins} were
   a threat
   VALUED OBJECT {to the local fishing industry}
2. an imagined threat
   AGGRESSOR {from the few remaining
   ex-revolutionaries}

A further way in which frame semantics can benefit lexical description is that is enables us to take a set of supposed synonyms and to use the theory to elucidate crucial differences of meaning and distribution – and incidentally show up the inadequacies of definitions in several current dictionaries. This has been demonstrated in Atkins's analysis of the verbs of seeing (1994). Comparing approaches to defining the verbs *behold*, *descry*, *notice*, *spot*, and *spy* in two mother tongue dictionaries, she notes how the verbs are defined in terms of each other. She is also aware that recourse to corpus data alone, rich though it may be, does not enable one to identify the tiny shifts of sense which divide one verb from another (Cowie, 1999).

Atkins's approach, in the case of the verbs *see*, *behold*, *catch sight of*, *spot*, *spy* is to recognize a 'perception frame,' whose chief elements include a 'passive' rather than an 'active experiencer' (since seeing, unlike looking, does not include an element of volition), a 'percept' (or object perceived) and a 'judgment,' which refers to the opinion which the experiencer forms of the percept as a result of seeing, etc. In the first example below, the judgment being made is comparative, while in the second example it is in the nature of an inference:

He looked to me like a yellow budgerigar.
(judgment–simile)
Peter looks relaxed. (judgment–inference)

As we can see from these examples, the relationship between semantic frame elements and grammatical functions is often far from straightforward. In the first example above, the experiencer is realized as the prepositional phrase *to me*; in a sentence such as *Mary saw the duck*, the experiencer is *Mary*, the subject of the perception verb *see* (Atkins, 1994: 5).

The work described briefly here forms part of a continuing descriptive project, of considerable scope and ambition, whose results are already proving invaluable to lexicographers and computational linguists.

Lexicon Grammars

A Geyken, Berlin-Brandenburg Academy of Sciences, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

History

The term '*lexique-grammar*' (lexicon-grammar) was introduced by Maurice Gross in 1984, but its basic principles were established already in the 1950s by Zellig Harris. However, despite the linguistic insights revealed by Harris's transformational methods, Harris has never tried his method on more than a handful of examples. The large-scale implementation of Harris's ideas was the merit of Gross, his student at the University of Pennsylvania. After returning to Paris in the late 1960s, Gross founded a research laboratory, LADL (*Laboratoire d'Automatique Documentaire et Linguistique*), where he and his team began to build a very large empirically based inventory of a lexicon-grammar of French.

In 1975, Gross published *Méthodes en syntaxe,* which lays the foundations for the methodology of lexicon-grammars. *Méthodes* also contains a complete and systematic description of French verbs that select for sentential complements. Two additional publications (Boons *et al.*, 1976; Guillet and Leclère, 1992) describe simple verbs without sentential complements. A large class of verb–complement combinations could not be characterized in terms of selectional restrictions. They are described by M. Gross (1981). Several lexicon-grammars about support verb constructions followed: Vivès (1983), Giry-Schneider (1987), and G. Gross (1988). Another focus of intense research was fixed expressions (M. Gross, 1982). Finally, lexicon-grammars have also been applied to other lexical forms: adjectives (Meunier, 1981), adverbs (M. Gross, 1990), and compound nouns (G. Gross, 1990).

Lexicon-grammars have been applied to the study of languages as diverse as Arabic, Chinese, English, French, German, Greek, Italian, Japanese, and Korean. Since 1981, RELEX, the international network of research on lexicon-grammars, organizes annual conferences devoted to lexis and grammar.

At the very basis of lexicon-grammars are the morphological DELA lexicons (DELA is an acronym for Electronic Dictionary of the LADL), which serve as index keys to the lexicon-grammars. DELA consists of several sublexicons: a lexicon of simple forms, containing 90 000 lemmas with complete morphological information, a lexicon containing phonemic information, and a lexicon of compound nouns with about 100 000 entries. The DELA lexicon format has been applied to English, Italian, German, Greek, Norwegian, Portuguese, and Spanish.

Maurice Gross's death slowed the momentum of lexicon-grammar development. A special issue of *Linguisticae Investigationes* in his honor, with more than 50 contributions, shows, however, that research in lexicon-grammar is still active (Leclère *et al.*, 2004).

Goals and Assumptions of Lexicon-Grammar

The goal of lexicon-grammar is to give a precise and complete description of the senses and usages of lexical units in elementary sentences on the basis of distributional and transformational methods (M. Gross, 1990: 39).

The lexicon-grammar approach is built upon the following important assumptions:

- The minimal context of linguistic description is the elementary sentence, i.e., a verb with only its essential complements (or strictly subcategorized complements in the terminology of generative grammar), and not the word. As a consequence, lexicon-grammars make no strict separation between lexicon and grammar.
- The transformational description in lexicon-grammar is based on Z. H. Harris's theoretical framework. Since Harris's transformations preserve the meaning of elementary sentences, lexicon-grammar describes meanings and not merely constructions.
- The approach is empirical since the syntactic behavior of lexical units is believed to be too idiosyncratic to be described with general rules. Rather than proceeding from a theory, Maurice Gross insists on a systematic description of the syntactic behavior of all or at least a large number of lexical elements of a language before deriving general rules (M. Gross, 1975: 46).

The Elementary Sentence

An elementary sentence consists of a predicative lexical unit and its essential complements. In accordance with valence theory, essential complements cannot be added freely to predicative lexical forms. In the case of verbs, the elementary sentences are of the form *P*:= *N0 V W*, where N0 is the subject, V the verb, and *W* an arbitrary sequence of verb complements. Lexicon-grammar claims that the form of an elementary sentence cannot be determined *a priori* but has to be discovered empirically for each lexical unit "since tests for characterizing essential complements

are highly lexical and tend to apply more to individual verbs or small groups rather than to broad classes" (M. Gross, 1996).

The main principle of lexicon-grammar is that the elementary sentence is taken as the minimal unit for the study of meaning and syntax, for several reasons. First, sentential idioms such as *Max took the bull by the horns* constitute elementary units of meaning. Likewise, noncompositional expressions such as compound nouns show that words are not always the minimal unit of meaning. Further, predicative lexical elements can only be fully described in their elementary sentence context, which is more than a description of verb–argument structure. Indeed, a fine-grained analysis reveals that more syntactic properties than is commonly assumed depend on the verb. For example, determiners or adjectives are mostly described as being constrained by their noun. However, in (1) and (2) they are shown to be verb-specific (M. Gross, 1993):

(1) Bob wants some beer * Bob loves some beer (quantifier reading)

(2) Bob is building a future mansion = Bob is building a mansion

Bob is eating a future cake ≠ Bob is eating a cake

Current linguistic models share the view that grammar and lexicon interact. However, this assumption was remarkable in a period when the overwhelming majority of linguists strictly separated lexical and grammatical levels. In contrast to this traditional point of view, lexicon-grammars assume that lexical units always carry grammatical information and, vice versa, what is traditionally described by grammars depends very much on lexical variability.

Transformations

Transformational rules in lexicon-grammar are based on Harris's theoretical framework (e.g., Harris, 1957, 1964). Unlike the transformational rules of early generative grammar, rejected by Gross because of the problematic status of their constituents (M. Gross, 1978), Harris's transformations operate on what generative grammar would call surface structure, i.e., on sequences of word classes (constructions) and their distributions (k-occurrences).

Constructions are sequences of elementary classes (noun, verb, adjective, article, preposition, conjunction, adverb) and morphemes (i.e., affixes). K-occurrences define the paradigmatic set of acceptable lexical units of sequences of elementary classes. For example, the k-occurrence of all adjectives occurring with the noun *property* in an adjective–noun sequence is determined by the set {*legal*, *small*, *common*, *immovable* . . .}, which is different from the entire class of all adjectives (**sallow property*, **yellow property*).

Two or more constructions are transformations of one another if they:

a. share the same set of elementary classes (affixes, auxiliaries, or promorphemes such as pronouns are not considered),
b. have the same k-occurrence, and
c. have the same broad distribution, i.e., occur in the same sentence environment.

Harris's transformations are equivalence classes if the homonyms of lexical units are distinguished. If homonyms are not distinguished, transformations are neither symmetric nor transitive. For example, the passive transformation in *The wreck was seen by the seashore* cannot be reversed because of the homonymy of the *by* construction (Harris, 1957: 395). Transformations thus preserve meaning, as summarized by Harris (1957: 395): "That many sentences which are transforms of each other have more or less the same meaning except for different external grammatical status . . . is an immediate impression. This is not surprising, since meaning correlates closely with the range of occurrence, and transformations maintain the same occurrence range."

One consequence of (c) is that while Harris's transformations operate on sentences, they generally do not allow transformations between sentences and noun phrases. For example, for the sentence *King John attacks the city*, Harris (Harris, 1964) formulates the relation of nominalization in (3) rather than (4), as suggested by early versions of generative grammar:

(3) King John launches an attack against the city

(4) the attack of the city by King John

This relation of nominalization led to the notion of support verb, a type of construction where the selectional constraints are not between the verb and the complements, but between the predicative noun and its complement. Again, this is justified by a transformational approach. Consider for example (5), a sentence that has the same surface structure as (3). However, the two constructions differ with respect to extraposition. Here, the double analysis holds for support verb constructions (7a), whereas it is not acceptable for the distributional verbs in (7b).

Constructing Lexicon-Grammars

The main motivation for constructing a lexicon-grammar is to determine systematically the rules of a language and their range of application. This process is illustrated here for verbs, but it works similarly for other predicative elements. The description of verbs and the selection of distributional and transformational properties were carried out by the linguists in Gross's team in an interdependent process. For two sentences with a given verb, it had to be determined whether the sentences had the same meaning or whether they could be related by transformations. Or, if the meaning was different, the goal was to find a transformation that was acceptable for one but not the other. For example, the different meanings of the morphological verb *arroser* ('to water') in the two following sentences can be demonstrated by the following reciprocal transformation:

(8) Luc arrose la plante avec un arrosoir = *Luc et l'arrosoir arrosent la plante
'Luc waters the plant with a can' = '*Luc and the can water the plant'

(9) Luc arrose la nouvelle année avec ses amis = Luc et ses amis arrosent la nouvelle année
'Luc toasts (lit.: waters) the New Year with his friend' = 'Luc and his friends toast the New Year'

Another goal is to mark all the syntactic properties for each verbal entry, i.e., the elementary sentence of the form subject-verb-essential complements. Judgments of acceptability are binary: an entry does or does not have a certain property. In order to correct the shortcomings of introspection that underestimate the actual production of forms (M. Gross, 1975), as a rule of thumb, dubious syntactic properties were marked as acceptable (M. Gross, 1996). Even though lexicon-grammars were constructed long before large electronic corpora were available for collecting attested data, this procedure has been criticized as leading to biased judgments and the acceptance of far too many properties (Busse, 1980).

Results and Discussion

More than 30 years of systematic description by a team of linguists have resulted in a huge lexicon grammar of French elementary sentences based on predicative lexical units. It consists of:

- 12 000 verbs organized according to 500 properties (stored as 15 000 verbal entries)
- 44 000 entries of fixed sentences
- 50 000 support verb constructions
- 7000 frozen adverbs (e.g., *back and forth*).

These units are stored in matrices where each line is an entry and each column corresponds to either a distributional or a transformational property. The cells are populated by a '+' if the property holds for the entry or a '−' if it does not. Since there is considerable redundancy in these matrices, entries are grouped together in submatrices, called classes, if they have similar syntactic properties. A sample of the matrix-representation is given in Table 1. A detailed description of the organization of French lexicon-grammar as well as the statistical distribution of all constructions can be found in Leclère (2002).

A comparison of all the lines of the matrix revealed that only a few verbs share the same set of constructions. This finding can be seen as an *a posteriori* justification of the lexicon grammar's methodology: "every verb has to be described on an individual basis" (M. Gross, 1996).

Lexicon-grammars separate meanings by applying the theoretical framework of Harris, but they have nothing to say on how the different entries are related. For example, the literal meaning and metaphorical uses of entries such as (8) and (9) can be separated by differences in form but they are unrelated. Laporte comments this as "the price to be paid for an essential epistemological feature: the model is designed so that it can be confronted with reality through a set of sufficiently reproducible experimental processes, which includes acceptability judgment, differential acceptability, paraphrase judgment, ambiguity judgment, and a few others, all applied to sentences" (Laporte, 2004).

Introduction

Generative Lexicon (GL) introduces a knowledge representation framework that offers a rich and expressive vocabulary for lexical information. The motivations for this are twofold. Overall, GL is concerned with explaining the creative use of language; we consider the lexicon to be the key repository holding much of the information underlying this phenomenon. More specifically, however, it is the notion of a constantly evolving lexicon that GL attempts to emulate; this is in contrast to currently prevalent views of static lexicon design, where the set of contexts licensing the use of words is determined in advance, and there are no formal mechanisms offered for expanding this set.

One of the most difficult problems facing theoretical and computational semantics is defining the representational interface between linguistic and nonlinguistic knowledge. GL was initially developed as a theoretical framework for encoding selectional knowledge in natural language. This in turn required making some changes in the formal rules of representation and composition. Perhaps the most controversial aspect of GL has been the manner in which lexically encoded knowledge is exploited in the construction of interpretations for linguistic utterances. Following standard assumptions in GL, the computational resources available to a lexical item consist of the following four levels:

(1a) Lexical typing structure: giving an explicit type for a word positioned within a type system for the language;
(1b) Argument structure: specifying the number and nature of the arguments to a predicate;
(1c) Event structure: defining the event type of the expression and any subeventual structure it may have with subevents;
(1d) Qualia structure: a structural differentiation of the predicative force for a lexical item.

The qualia structure, inspired by Moravcsik's (1975) interpretation of the *aitia* of Aristotle, are defined as the modes of explanation associated with a word or phrase in the language, and are defined as follows (Pustejovsky, 1991):

(2a) Formal: the basic category of which distinguishes the meaning of a word within a larger domain;
(2b) Constitutive: the relation between an object and its constituent parts;

Lexicon, Generative

Introduction

Generative Lexicon (GL) introduces a knowledge representation framework that offers a rich and expressive vocabulary for lexical information. The motivations for this are twofold. Overall, GL is concerned with explaining the creative use of language; we consider the lexicon to be the key repository holding much of the information underlying this phenomenon. More specifically, however, it is the notion of a constantly evolving lexicon that GL attempts to emulate; this is in contrast to currently prevalent views of static lexicon design, where the set of contexts licensing the use of words is determined in advance, and there are no formal mechanisms offered for expanding this set.

One of the most difficult problems facing theoretical and computational semantics is defining the representational interface between linguistic and nonlinguistic knowledge. GL was initially developed as a theoretical framework for encoding selectional knowledge in natural language. This in turn required making some changes in the formal rules of representation and composition. Perhaps the most controversial aspect of GL has been the manner in which lexically encoded knowledge is exploited in the construction of interpretations for linguistic utterances. Following standard assumptions in GL, the computational resources available to a lexical item consist of the following four levels:

(1a) Lexical typing structure: giving an explicit type for a word positioned within a type system for the language;
(1b) Argument structure: specifying the number and nature of the arguments to a predicate;
(1c) Event structure: defining the event type of the expression and any subeventual structure it may have with subevents;
(1d) Qualia structure: a structural differentiation of the predicative force for a lexical item.

The qualia structure, inspired by Moravcsik's (1975) interpretation of the *aitia* of Aristotle, are defined as the modes of explanation associated with a word or phrase in the language, and are defined as follows (Pustejovsky, 1991):

(2a) Formal: the basic category of which distinguishes the meaning of a word within a larger domain;
(2b) Constitutive: the relation between an object and its constituent parts;

(2c) Telic: the purpose or function of the object, if there is one;
(2d) Agentive: the factors involved in the object's origins or 'coming into being.'

Conventional interpretations of the GL semantic representation have been as feature structures (cf. Bouillon, 1993; Pustejovsky, 1995). The feature representation shown below gives the basic template of argument and event variables, and the specification of the qualia structure.

$$\begin{bmatrix} \alpha & \\ \text{ARGSTR} = & \begin{bmatrix} \text{ARG1} = x \\ \ldots \end{bmatrix} \\ \text{EVENTSTR} = & \begin{bmatrix} \text{E1} = e^1 \\ \ldots \end{bmatrix} \\ \text{QUALIA} = & \begin{bmatrix} \text{CONST} = \textbf{what } x \textbf{ is made of} \\ \text{FORMAL} = \textbf{what } x \textbf{ is} \\ \text{TELIC} = \textbf{function of } x \\ \text{AGENTIVE} = \textbf{how } x \textbf{ came into being} \end{bmatrix} \end{bmatrix}$$

Traditional Lexical Representations

The traditional organization of lexicons in both theoretical linguistics and natural language processing systems assumes that word meaning can be exhaustively defined by an enumerable set of senses per word. Lexicons, to date, generally tend to follow this organization. As a result, whenever natural language interpretation tasks face the problem of lexical ambiguity, a particular approach to disambiguation is warranted. The system attempts to select the most appropriate 'definition' available under the lexical entry for any given word; the selection process is driven by matching sense characterizations against contextual factors. One disadvantage of such a design follows from the need to specify, ahead of time, the contexts in which a word might appear; failure to do so results in incomplete coverage. Furthermore, dictionaries and lexicons currently are of a distinctly static nature: the division into separate word senses not only precludes permeability; it also fails to account for the creative use of words in novel contexts.

GL attempts to overcome these problems, both in terms of the expressiveness of notation and the kinds of interpretive operations the theory is capable of supporting. Rather than taking a 'snapshot' of language at any moment of time and freezing it into lists of word sense specifications, the model of the lexicon proposed here does not preclude extensibility: it is open-ended in nature and accounts for the novel, creative uses of words in a variety of contexts by positing procedures for generating semantic expressions for words on the basis of particular contexts.

Adopting such a model presents a number of benefits. From the point of view of a language user, a rich and expressive lexicon can explain aspects of learnability. From the point of view of linguistic theory, it can offer improvements in robustness of coverage. Such benefits stem from the fact that the model offers a scheme for explicitly encoding lexical knowledge at several levels of generalization. In particular, by making lexical ambiguity resolution an integral part of a uniform semantic analysis procedure, the problem is rephrased in terms of dynamic interpretation of a word in context; this is in contrast to current frameworks which select among a static, predetermined set of word senses, and do so separately from constructing semantic representations for larger text units.

There are several methodological motivations for importing tools developed for the computational representation and manipulation of knowledge into the study of word meaning, or lexical semantics. Generic knowledge representation (KR) mechanisms, such as inheritance structures or rule bases, can – and have been – used for encoding linguistic information. However, not much attention has been paid to the notion of what exactly constitutes such linguistic information. Traditionally, the application area of knowledge representation formalisms has been the domain of general world knowledge. By shifting the focus to a level below that of words (or lexical concepts) one is able to abstract the notion of lexical meaning away from world knowledge, as well as from other semantic influences such as discourse and pragmatic factors. Such a process of abstraction is an essential prerequisite for the principled creation of lexical entries.

Although GL makes judicious use of knowledge representation (KR) tools to enrich the semantics of lexical expressions, it preserves a felicitous partitioning of the information space. Keeping lexical meaning separate from other linguistic factors, as well as from general world knowledge, is a methodologically sound principle; nonetheless, GL maintains that all of these should be referenced by a lexical entry. In essence, such capabilities are the base components of a generative language whose domain is that of lexical knowledge. The interpretive aspect of this language embodies a set of principles for richer composition of components of word meaning. As illustrated later in this entry, semantic expressions for word meaning in context are constructed by a fixed number of generative devices (cf. Pustejovsky, 1991). Such devices operate on a core set of senses (with greater internal structure than hitherto assumed); through composition, an extended set of word senses is obtained when individual lexical items are considered jointly with others in larger phrases. The language

presented below thus becomes an expressive tool for capturing lexical knowledge, without presupposing finite sense enumeration.

The Nature of Polysemy

One of the most pervasive phenomena in natural language is that of systematic ambiguity, or polysemy. This problem confronts language learners and natural language processing systems alike. The notion of context enforcing a certain reading of a word, traditionally viewed as selecting for a particular word sense, is central both to global lexical design (the issue of breaking a word into word senses) and local composition of individual sense definitions. However, current lexicons reflect a particularly 'static' approach to dealing with this problem: the numbers of and distinctions between senses within an entry are 'frozen' into a fixed grammar's lexicon. Furthermore, definitions hardly make **any** provisions for the notion that boundaries between word senses may shift with context – not to mention that no lexicon really accounts for any of a range of lexical transfer phenomena.

There are serious problems with positing a fixed number of 'bounded' word senses for lexical items. In a framework that assumes a partitioning of the space of possible uses of a word into word senses, the problem becomes that of selecting, on the basis of various contextual factors (typically subsumed by, but not necessarily limited to, the notion of selectional restrictions), the word sense closest to the use of the word in the given text. As far as a language user is concerned, the question is that of 'fuzzy matching' of contexts; as far as a text analysis system is concerned, this reduces to a search within a finite space of possibilities.

This approach fails on several accounts, both in terms of what information is made available in a lexicon for driving the disambiguation process, and how a sense selection procedure makes use of this information. Typically, external contextual factors alone are not sufficient for precise selection of a word sense; additionally, often the lexical entry does not provide enough reliable pointers to critically discriminate between word senses. In the case of automated sense selection, the search process becomes computationally undesirable, particularly when it has to account for longer phrases made up of individually ambiguous words. Finally, and most importantly, the assumption that an exhaustive listing can be assigned to the different uses of a word lacks the explanatory power necessary for making generalizations and/or predictions about how words used in a novel way can be reconciled with their currently existing lexical definitions.

To illustrate this last point, consider the ambiguity and context-dependence of adjectives such as *fast* and *slow*, where the meaning of the predicate varies depending on the noun being modified. Sentences (3a)–(3e) show the range of meanings associated with the adjective *fast*. Typically, a lexicon requires an enumeration of different senses for such words, to account for this ambiguity:

(3a) The island authorities sent out a <u>fast</u> little government <u>boat</u> to welcome us:
Ambiguous between a boat driven quickly/one that is inherently fast.

(3b) a <u>fast typist:</u>

a person who performs the act of typing quickly.

(3c) Rackets is a <u>fast game</u>:
the motions involved in the game are rapid and swift.

(3d) a <u>fast book</u>:
one that can be read in a short time.

(3e) My friend is a <u>fast driver</u> and a constant worry to her cautious husband:
one who drives quickly.

These examples involve at least four distinct word senses for the word *fast*, (WordNet 2.0 has ten senses for the adjectival reading of *fast*.):

fast (1): moving quickly;
fast (2): performing some act quickly;
fast (3): doing something requiring a short space of time;
fast (4): involving rapid motion.

In an operational lexicon, word senses would be further annotated with selectional restrictions: for instance, fast (1) may be predicated by the object belonging to a class of movable entities, and fast (3) may relate the action 'that takes a little time' – e.g., reading, in the case of (4) below – to the object being modified. Upon closer analysis, each occurrence of *fast* above predicates in a slightly different way. In fact, any finite enumeration of word senses will not account for creative applications of this adjective in the language. For example, consider the two phrases *fast freeway* and *fast garage*. The adjective *fast* in the phrase *a fast freeway* refers to the ability of vehicles on the freeway to sustain high speed, while in *fast garage* it refers to the length of time needed for a repair. As novel uses of *fast*, we are clearly looking at new senses that are not covered by the enumeration given above.

Part of GL's argument for a different organization of the lexicon is based on a claim that the boundaries between the word senses in the analysis of *fast* above are too rigid. Still, even if we assume that enumeration is adequate as a descriptive mechanism, it is not

always obvious how to select the correct word sense in any given context: consider the systematic ambiguity of verbs like *bake* (discussed by Atkins *et al.*, 1988), which require discrimination with respect to change-of-state versus create readings, depending on the context (see sentences [4a] and [4b], respectively).

(4a) *John baked the potatoes.*
(4b) *Mary baked a cake.*

The problem here is that there is too much overlap in the 'core' semantic components of the different readings (Jackendoff (1985) correctly points out, however, that deriving one core meaning for all homographs of a word form may not be possible, a view not inconsistent with that proposed here.); hence, it is not possible to guarantee correct word sense selection on the basis of selectional restrictions alone. Another problem with this approach is that it lacks any appropriate or natural level of abstraction.

As these examples clearly demonstrate, partial overlaps of core and peripheral components of different word meanings make the traditional notion of word sense, as implemented in current dictionaries, inadequate. Within this approach, the only feasible solution would be to employ a richer set of semantic distinctions for the selection of complements than is conventionally provided by the mechanism of selectional restrictions.

It is equally arbitrary to create separate word senses for a lexical item just because it can participate in several subcategorization forms; yet this has been the only approach open to computational lexicons that are based on a fixed number of features and senses. A striking example of this is provided by verbs such as *believe* and *forget*. The sentences in (5a)–(5b) show that the syntactic realization of the verb's object complement determines how the phrase is interpreted semantically. The *that-complement*, for example, in (5a) exhibits a property called factivity (Kiparsky and Kiparsky, 1971), where the object proposition is assumed to be a fact regardless of what modality the whole sentence carries. Sentence (5d) contains a 'concealed question' complement (Grimshaw, 1979), so called because the phrase can be paraphrased as a question. These different interpretations are usually encoded as separate senses of the verb, with distinct lexical entries.

(5a) Mary <u>forgot that</u> she left the light on at home.
(a factive reading)
(5b) Mary <u>forgot to</u> leave the light on for the delivery man.
(a nonfactive reading)
(5c) I almost <u>forgot where</u> we're going.
(an embedded question)
(5d) She always <u>forgets the password</u> to her account.
(a concealed question)
(5e) He leaves, <u>forgets his umbrella</u>, comes back to get it . . .
(ellipsed nonfactive)

These distinctions could be easily accounted for by simply positing separate word senses for each syntactic type, but this misses the obvious relatedness between the different syntactic contexts of *forget*. Moreover, the general 'core' sense of the verb *forget*, which deontically relates a mental attitude with a proposition or event, is lost between the separate senses of the verb. GL, on the other hand, posits one definition for *forget* which can, by suitable composition with the different complement types, generate all the allowable readings (cf. Pustejovsky, 1995).

Levels of Lexical Meaning

The richer structure for the lexical entry proposed in GL takes to an extreme the established notions of predicate-argument structure, primitive decomposition and conceptual organization; these can be seen as determining the space of possible interpretations that a word may have. That is, rather than committing to an enumeration of a predetermined number of different word senses, a lexical entry for a word now encodes a range of representative aspects of lexical meaning. For an isolated word, these meaning components simply define the semantic boundaries appropriate to its use. When embedded in the context of other words, however, mutually compatible roles in the lexical decompositions of each word become more prominent, thus forcing a specific interpretation of individual words within a specific phrase. It is important to realize that this is a generative process, which goes well beyond the simple matching of features. In fact, this approach requires, in addition to a flexible notation for expressing semantic generalizations at the lexical level, a mechanism for composing these individual entries on the phrasal level.

The emphasis of our analysis of the distinctions in lexical meaning is on studying and defining the role that **all** lexical types play in contributing to the overall meaning of a phrase. Crucial to the processes of semantic interpretation that the lexicon is targeted for is the notion of compositionality, necessarily different from the more conventional pairing of verbs as functions and nouns as arguments. If the semantic load in the lexicon is entirely spread among the verb entries, as many existing lexicons assume, differences like those exemplified above can only be accounted for by treating *bake, forget*, and so forth as polysemous verbs. If, on the other hand, elaborate lexical meanings of verbs and adjectives could be made sensitive to

components of equally elaborate decompositions of nouns, the notion of spreading the semantic load evenly across the lexicon becomes the key organizing principle in expressing the knowledge necessary for disambiguation.

To be able to express the lexical distinctions required for analyzing the examples in the last section, it is necessary to go beyond viewing lexical decomposition as based only on a predetermined set of primitives; rather, what is needed is to be able to specify, by means of sets of predicates, different levels or perspectives of lexical representation, and to be able to compose these predicates via a fixed number of generative devices. The 'static' definition of a word provides its literal meaning; it is only through the suitable composition of appropriately highlighted projections of words that we generate new meanings in context.

In order to address these phenomena and inadequacies mentioned above, Generative Lexicon argues that a theory of computational lexical semantics must make reference to the four levels of representations mentioned above:

1. **Lexical Typing Structure**. This determines the ways in which a word is related to other words in a structured type system (i.e., *inheritance*. In addition to providing information about the organization of a lexical knowledge base, this level of word meaning provides an explicit link to general world (commonsense) knowledge.
2. **Argument Structure**. This encodes the conventional mapping from a word to a function, and relates the syntactic realization of a word to the number and type of arguments that are identified at the level of syntax and made use of at the level of semantics (Grimshaw, 1991);
3. **Event Structure**. This identifies the particular event type for a verb or a phrase. There are essentially three components to this structure: the primitive event type – state (**S**), process (**P**), or transition (**T**); the focus of the event; and the rules for event composition (cf. Moens and Steedman, 1988; Pustejovsky, 1991b).
4. **Qualia Structure**. This defines the essential attributes of objects, events, and relations, associated with a lexical item. By positing separate components (see below) in what is, in essence, an argument structure for nominals, nouns are elevated from the status of being passive arguments to active functions (cf. Moravcsik, 1975; Pustejovsky, 1991a). We can view the fillers in qualia structure as prototypical predicates and relations associated with this word.

A set of generative devices connects the four levels, providing for the compositional interpretation of words in context. These devices include subselection, type coercion, and cocomposition. In this article, we will focus on the qualia structure and type coercion, an operation that captures the semantic relatedness between syntactically distinct expressions. As an operation on types within a λ-calculus, type coercion can be seen as transforming a fixed semantic language into one with changeable (polymorphic) types. Argument, event, and qualia types must conform to the well-formedness conditions defined by the type system and the lexical inheritance structure when undergoing operations of semantic composition. Lexical items are strongly typed yet are provided with mechanisms for fitting to novel typed environments by means of type coercion over a richer notion of types.

Qualia Structure

Qualia structure is a system of relations that characterizes the semantics of a lexical item, very much like the argument structure of a verb (Pustejovsky). To illustrate the de scriptive power of qualia structure, the semantics of nominals will be the focus here. In effect, the qualia structure of a noun determines its meaning in much the same way as the typing of arguments to a verb determines its meaning. The elements that make up a qualia structure include familiar notions such as container, space, surface, figure, or artifact. One way to model the qualia structure is as a set of constraints on types (cf. Copestake and Briscoe, 1992; Pustejovsky and Boguraev, 1993). The operations in the compositional semantics make reference to the types within this system. The qualia structure along with the other representational devices (event structure and argument structure) can be seen as providing the building blocks for possible object types. Figure 1 illustrates a type hierarchy fragment for knowledge about objects, encoding qualia structure information. In Figure 1, the term `nomrqs` refers to a 'relativized qualia structure' a type of generic information structure for entities (cf. Calzolari, 1992 for discussion). Further, `ind.obj` represents 'individuated object.'

Figure 1 Type hierarchy fragment.

The tangled type hierarchy above shows how qualia can be unified to create more complex concepts out of simple ones. Following Pustejovsky (2001, 2005), we can distinguish the domain of individuals into three ranks or levels of type:

(6a) Natural Types: Natural kind concepts consisting of reference only to Formal and Const qualia roles;
(6b) Functional Types: Concepts integrating reference to purpose or function.
(6c) Complex Types: Concepts integrating reference to a relation between types.

For example, a simple natural physical object (7), can be given a function (i.e., a Telic role), and transformed into a functional type, as in (8).

(7) $\begin{bmatrix} \textbf{physobj (x)} \\ \text{FORMAL} = \textbf{physform (x)} \end{bmatrix}$

(8) $\begin{bmatrix} \textbf{artifact_obj(x)} \\ \text{FORMAL} = \textbf{physform (x)} \\ \text{TELIC} = \textbf{Pred (E,y,x)} \end{bmatrix}$

Functional types in language behave differently from naturals, as they carry more information with them regarding their use and purpose. For example, the noun *sandwich* contains information of the 'eating activity' as a constraint on its *Telic* value, due to its position in the type structure; that is, **eat(P,w,x)** denotes a process, **P**, between an individual **w** and the physical object **x**.

(9) $\begin{bmatrix} \textbf{sandwich(x)} \\ \text{CONST} = \{\textbf{bread,...}\} \\ \text{FORMAL} = \textbf{physobj}(\text{x}) \\ \text{TELIC} = \textbf{eat (P,w,x)} \\ \text{AGENTIVE} = \textbf{artifact (x)} \end{bmatrix}$

From qualia structures such as these, it now becomes clear how a sentence such as *Mary finished her sandwich* receives the default interpretation it does; namely, that of Mary eating the sandwich. This is an example of *type coercion*, and the semantic compositional rules in the grammar must make reference to values such as qualia structure, if such interpretations are to be constructed on-line and dynamically.

Coercion and Compositionality

Type coercion is an operation in the grammar ensuring that the selectional requirements on an argument to a predicate are in fact satisfied by the argument in the compositional process. The rules of coercion presuppose a typed ontology such as that outlined above. By allowing lexical items to coerce their arguments, we obviate the enumeration of multiple entries for different senses of a word. We define coercion as follows (Pustejovsky, 1995):

(10) **Type Coercion:** a semantic operation that converts an argument to the type that is expected by a function, where it would otherwise result in a type error.

The notion that a predicate can specify a particular target type for its argument is a very useful one, and intuitively explains the different syntactic argument forms for the verbs below. In sentences (11) and (12), noun phrases and verb phrases appear in the same argument position, somehow satisfying the type required by the verbs *enjoy* and *begin*. In sentences (13) and (14), noun phrases of very different semantic classes appear as subject of the verbs *kill* and *wake*.

(11a) Mary enjoyed <u>the movie</u>.
(11b) Mary enjoyed <u>watching the movie</u>.

(12a) Mary began <u>a book</u>.
(12b) Mary began <u>reading a book</u>.
(12c) Mary began <u>to read a book</u>

(13a) <u>John</u> killed Mary.
(13b) <u>The gun</u> killed Mary.
(13c) <u>The bullet</u> killed Mary.

(14a) <u>The cup of coffee</u> woke John up.
(14b) <u>Mary</u> woke John up.
(14c) <u>John's drinking the cup of coffee</u> woke him up.

If we analyze the different syntactic occurrences of the above verbs as separate lexical entries, following the sense enumeration theory outlined in previous sections, we are unable to capture the underlying relatedness between these entries; namely, that no matter what the syntactic form of their arguments, the verbs seem to be interpreting all the phrases as events of some sort. It is exactly this type of complement selection that type coercion allows in the compositional process.

Complex Types in Language

One of the more unique aspects of the representational mechanisms of GL is the data structure known as a complex type (or dot object), introduced to explain several phenomena involving the selection of conflicting types in syntax. There are well-known cases of container-containee and figure-ground ambiguities, where a single word may refer to two aspects of an object's meaning (cf. Apresjan, 1973; Wilks, 1975; Lakoff, 1987; Pustejovsky and Anick, 1988). The words *window, door, fireplace*, and *room* can be used to refer to the physical object itself or the space associated with it:

(15a) They walked through the door.
(15b) She will paint the door red.

(16a) Black smoke filled the fireplace.
(16b) The fireplace is covered with soot.

In addition to figure-ground and container-containee alternations, there are many other cases in natural language where two or more aspects of a concept are denoted by a single lexicalization. As with nouns such as *door*, the nouns *book* and *exam* denote two contradictory types; books are both physical form and informational in nature; exams are both events and informational.

(17a) Mary doesn't believe the book.
(17b) John bought his book from Mary.
(17c) The police burnt a controversial book.

(18a) John thought the exam was confusing.
(18b) The exam lasted more than two hours this morning.

What is interesting about the above pairs is that the two senses of these nouns are related to one another in a specific way. The apparently contradictory nature of the two senses for each pair actually reveals a deeper structure relating these senses, something that is called a dot object. For each pair, there is a relation that connects the senses, represented as a Cartesian product of the two semantic types. There must exist a relation *R* that relates the elements of the pairing, and this relation must be part of the definition of the semantics for the dot object to be well-formed. For nouns such as *book*, *disk*, and *record*, the relation *R* is a species of 'containment,' and shares grammatical behavior with other container-like concepts. For example, we speak of information **in** a book, articles **in** the newspaper, as well as songs **on** a disc. This containment relation is encoded directly into the semantics of a concept such as *book* – i.e., *hold*(*x, y*) – as the formal quale value. For other dot object nominals such as *prize*, *sonata*, and *lunch*, different relations will structure the types in the Cartesian product, as we see below. The lexical structure for *book* as a dot object can be represented as in (19).

(19)
$$\begin{bmatrix} \textbf{book} & \\ \text{ARGSTR} = & \begin{bmatrix} \text{ARG1} = \text{y: information} \\ \text{ARG2} = \text{x: phys-obj} \end{bmatrix} \\ \text{QUALIA} = & \begin{bmatrix} \text{FORM} = \text{hold (x,y,)} \\ \text{TELIC} = \text{read (e,w, x.y)} \\ \text{AGENT} = \text{write (é, v, x.y)} \end{bmatrix} \end{bmatrix}$$

Nouns such as *sonata*, *lunch*, and *appointment*, on the other hand, are structured by entirely different relations.

Recent Developments in Generative Lexicon

As the theory has matured, many of the analytic devices and the linguistic methodology of Generative Lexicon have been extended and applied to languages and phenomena well beyond the original scope of the theory. Cocomposition has been applied to a number of phenomena, particularly light verb constructions, with a fair amount of success, in Korean and Japanese (Lee *et al.*, 2003). Qualia structure has proved to be an expressive representational device and has been adopted by adherents of many other grammatical frameworks. For example, Jensen and Vikner (1994) and Borschev and Partee (2001) both appeal to qualia structure in the interpretation of the genitive relation in NPs, while many working on the interpretation of noun compounds have developed qualia-based strategies for interpretation of noun–noun relations (Johnston and Busa, 1996, 1997; Lehner, 2003; Jackendoff, 2003). Van Valin (2005) has adopted qualia roles within several aspects of RRG analyses, where nominal semantics have required finer grained representations.

Perhaps one of the biggest developments within the theory in recent years has been the integration of type coercion into a general theory of the mechanisms of selection in grammar (Pustejovsky, 2002, 2005). On this view, there are three mechanisms that account for all local syntagmatic and paradigmatic behavior in the grammar: pure selection, type exploitation, and type coercion.

The challenges posed by Generative Lexicon to linguistic theory are quite direct and simple: semantic interpretation is as creative and generative as syntax if not more so. But the process operates under serious constraints and inherently restrictive mechanisms. It is GL's goal to uncover these mechanisms in order to model the expressive semantic power of language.

Lexicon: Structure

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

A lexicon is a bin for storing listemes, language expressions whose meaning is not determinable from the meanings (if any) of their constituent forms and that, therefore, a language user must memorize as a combination of form and meaning. The way that a lexicon is organized depends on what it is designed to do.

1. The traditional Indo-European desktop dictionary is organized into alphabetically ordered entries in order to maximize look-up efficiency for the literate user.
2. *Kitab al-Ayn*, the Arabic dictionary of Al Khalil Ben Ahmad, has a phonetically based listing, beginning with velars and ending with bilabials (Kniffka, 1994).
3. A grammar that requires random lexical entry according to morphological class needs to access a lexicon through the morphosyntactic category of the lexicon entry.
4. The hearer accesses the mental lexicon from the phonological or graphological form of the entry.
5. The speaker accesses the mental lexicon through the meaning. However, slips of the tongue suggest that access presents a choice among several activated forms, from among which the inappropriate ones need to be inhibited (Aitchison, 2003: 220).
6. Someone producing an alliteration (e.g., *around the rugged rocks the ragged rascal ran*) needs to access the onsets to phonological forms.
7. Someone looking for a rhyme needs to be able to access entries via the endings of the phonological form.
8. The meaning of one word can remind us of another with a similar or contrary meaning; this suggests that meanings in the lexicon must be organized into a network of relations similar to those in a thesaurus.

Summing up, a lexicon must be accessible from three directions – form, morphosyntax, and meaning – none of which is intrinsically prior.

Formal specifications include graphological specification such as alternative spellings, hyphenation location, and use of uppercase. The phonological specification includes information on alternative pronunciations, syllable weight and structure, and the relative pitch and/or tone of the various syllables.

Morphosyntactic specifications include morphological and syntactic properties such as the inherent morphosyntactic (lexical) category of the item. Traditionally, the nouns *helicopter* and *move* and the semantically related verbs *helicopter* and *move* are all different listemes; yet, despite their different syntactic properties and concomitant meaning differences, the transitive verb *move* and the intransitive verb *move* traditionally share the same polysemous dictionary entry under different subheadings. The *COBUILD English dictionary* lists all forms of a listeme; for example, for *clear* it has *clearer, clearest, clears, clearing, cleared* (not divided between Adj and V listemes). Derived words are either generated from the listeme by morphological rules (e.g., Adv *clearly* from Adj *clear*) or else listed as distinct listemes. Should dictionaries list just morphemes or every word form, including inflected forms, or something in between? For various views see Butterworth (1983), Flores d'Arcais and Jarvella (1983), Altman (1990), Altman and Shillcock (1993), Allan (2001), and Aitchison (2003). Regularities need to be signaled, for example, the declension and gender of Latin nouns and the conjugation of verbs. So, too, must irregularities be signaled, for example, the past tense of English strong verbs, and constraints on range such as an object NP can interrupt the V + vPrt of some phrasal verbs (*run* NP *down*; 'denigrate NP') but not others (*put* *NP *up with*; 'endure NP').

Semantic specifications identify the senses of a listeme based on the salient characteristics of its typical denotatum (*see* **Stereotype Semantics**). The form of the semantic specification depends on the preferred metalanguage (*see* **Metalanguage versus Object Language; Cognitive Semantics; Dynamic Semantics; Frame Semantics; Lexicon, Generative; Lexical Conceptual Structure; Natural Semantic Metalanguage**). Boguraev and Briscoe (1989: 5) add encyclopedic knowledge to the list of semantic specifications, and many lexicographers would agree that a lexicon should also be a cultural index; thus, the *Collins English dictionary* (Hanks, 1998), *New Oxford dictionary of English* (Pearsall, 1998), and *Collins English dictionary* (Butterfield, 2003) list encyclopedic information about bearers of certain proper names (on the networked relationship between lexicon and encyclopedia, *see* **Dictionaries and Encyclopedias: Relationship**).

Bauer (1983: 196) proposed a category of 'stylistic specifications' to distinguish among *piss, piddle*, and *micturate* to reflect the kind of metalinguistic information found in traditional desktop dictionary tags such as 'colloquial,' 'slang,' 'derogatory,' 'medicine,' and 'zoology.' Such metalinguistic information is more appropriate to the encyclopedia entry directly

connected with every lexicon entry. The encyclopedia will also supply etymological information, which is not essential to the proper use of the listemes, and an account of the connotations (*see* **Connotation**) of listemes, which is.

Bauer also suggested a signaling of 'related lexemes' such as that *edible* is related to *eat*. This should be identified through the semantic specification, which will differentiate the sense of *edible* from *eatable* (cf. Lehrer, 1990: 210). Contraries and antonyms are linked to a listeme via its semantic field (*see* **Lexical Fields**). Metalanguage terms used in semantic specifications are often semantically identical with object language listemes; for example, Pustejovsky (1995: 101) specified *book* as a "physical object" that "holds" "information" created by someone who "write[s]" it and whose function is to be "read." Certainly, there is a relation among *book*, *write*, and *read* that needs to be accounted for either in the semantic specification or the associated encyclopedia entry. Used in the morphosyntactic specifications, such category terms as *noun, verb*, *adjective*, and *feminine* are part of the metalanguage, not the object language. But they also appear in the lexicon as expressions in the object language. Suppose that the sense 'typically names a person, place, thing or abstract entity' has an address in the lexicon (this is explained later). Next, suppose that in the lexicon of English, one form at this address is *noun*; in the lexicon of French, one form at this address is *nom*; and in the lexicon of Greek, it is *όνομα*. Suppose that in the lexicon of the metalanguage there is a form N at this same address. This move simply reflects the well-known and widely accepted fact that there are translation (near) equivalences between the object language and metalanguage, just as there are between different natural languages. The lexicon is used in string matching among formal specifications, such as retrieving all listemes beginning with /d/ or those rhyming with *cord*. Similarly, a search of the morphosyntactic specification of every entry is the best way to compile a list of all nouns in the lexicon. And the semantic specification of a listeme will locate it within its semantic field and relate it to superordinate items, contraries, antonyms, and the like. Many of these relations are not primarily lexical but arise from the relationships characteristic of the denotatum of a listeme; for example, because a cat is perceived to be a kind of animal, the listeme *animal* is semantically superordinate to the listeme *cat*. Any two listemes may be connected through their formal, morphosyntactic, and/or semantic specifications in the lexicon and through the stylistic or etymological properties identified in the encyclopedia.

Figure 1 Jackendoff-style lexicon entry for *dog*.

Lyons (1977: 516) suggested that each lexicon entry be assigned a random number that serves as its address for access through any of the three modes. This proposal is very similar to one in Jackendoff (1995; 1997: 89), which "licence[s] the correspondence of certain (near-) terminal symbols of syntactic structure with phonological and conceptual structures" (*see* **Lexical Conceptual Structure**). Jackendoff proposed that a lexicon entry has the three parts, as shown in Figure 1, where they are tagged with our specification types.

In Jackendoff's theory, the morphosyntactic specification is the linchpin that is co-indexed $_j$ with the formal specification on the left-hand side and the subscript $_n$ of the semantic specifications on the right. This seems correct. If we ask someone the meaning of the word *fly* (which is many ways ambiguous), two possible answers are 'travel though the air' (V) and 'cloth cover for an opening' (N). Similarly, the word *dog* means 'canine animal' (N) and 'follow dog-like' (V). The word *canine* means 'a member of the dog family' (N) and 'pertaining to the dog family' (Adj). The difference between such pairs is indicated by the combination of formal and morphosyntactic specification – which corresponds to Jackendoff's subscript $_j$ in Figure 1. This distinguishing factor is exactly the reason that a traditional desktop dictionary identifies the morphosyntactic category immediately after identifying the form of a listeme. Example (1) shows how much morphosyntax contributes to meaning.

(1) the toves gimbled in the wabe

In this example, *toves* is clearly a plural noun and therefore denotes more than one entity, *gimbled* is the past tense of a verb and so denotes some act or state of the toves, and *wabe* is a noun – and, because it falls within the scope of the preposition *in*, *wabe* identifies a place or time. Thus, the morphosyntactic specification of these words gives us some meaning to work on, as suggested by Jackendoff's subscript $_n$ in Figure 1. In addition, the form distinguishes between the nouns *tove* and *wabe*.

For the speaker, the main function of the lexicon is to find a form to express the intended meaning – but

Figure 2 Networked components of an entry in the hypothetical lexicon. F, formal specs; M, morphosyntactic specs; S, semantic specs.

not just a form; it should also find its morphosyntactic category, which is often at least partly determined by the content. For instance, a reference to a thing will usually require using a noun; a reference to an event will usually require a verb. Except when parroting a phrase, it is impossible when speaking a language to use a form without assigning it a morphosyntactic specification. It is impossible to assign a morphosyntactic specification to a meaning without also assigning it a form (the appropriate form for a zero morph is, of course, null). Someone who asks *what's the word that means 'get back at'?* may not be able to retrieve the form *retaliate*, but the intended meaning is conveyed using the forms of other lexemes. In terms of Figure 1, the speaker goes from the subscript $_n$ on the semantic specification to the morphosyntactic specification $_jN_n$ that links to the formal specification through the $_j$ subscript. For the hearer, the main function of the lexicon is to attach meaning to forms that normally occur within syntactic structures, so it is a matter of finding a semantic specification for something that is both formally and morphosyntactically specified. In terms of Figure 1, the hearer goes from $_j$ to $_n$.

Jackendoff's subscripts correspond to connection points for bidirectional lines in a network as in Figure 2, which shows that their sequence with respect to the formal specifications (F), morphosyntactic specifications (M), and semantic specifications (S) is a convention without substance; that is, $_fF = F_f$ and so forth. Suppose there are the grossly oversimplified components in Table 1. The formal and semantic addresses are randomly selected numbers, tagged with $_f$ and $_s$, respectively.

Table 1 ignores (1) the fact that the semantic specifications must somehow reflect the facts that a dog is an animal, a living thing, and a physical object and (2) the need to identify the kind of countable and uncountable environments in which a noun can conventionally occur; the thematic structure, valency, or frame of a verb; and the gradability of an adjective. In Figure 3, which represents a part of this network of relations, the question of how the graphological and phonological forms should be correlated is not accounted for.

Table 1 Partial entries for *dog* and *canine*[a]

F	*M*	*S*
$_{f8899}$*dog*	$_{f8899}$N$_{s0017}$	**dog**$'_{s0017}$
	$_{f8899}$V$_{s3214}$	**follow_like_a**$__{s}$0017$'_{s3214}$
$_{f7656}$*canine*	$_{f7656}$N$_{s7439}$	**conical_pointed_tooth**$'_{s7439}$
	$_{f7656}$Adj$_{s1227}$	**pertaining_to_a**$__{s}$0017$'_{s1227}$

[a]F, formal specs; M, morphosyntactic specs; S, semantic specs.

Figure 3 Part of the network for the lexicon entries for *dog* (N and V) and *canine* (N and Adj).

The form of a lexicon entry is a co-indexed tripartite network in which the indices correspond to bidirectional connectors between the components of a lexicon entry, as shown in Figure 2. Each of the formal, morphosyntactic and semantic specifications is also linked with the encyclopedia (*see* **Dictionaries and Encyclopedias: Relationship**). Such connectors model cognitive pathways that presumably have a neurological basis and could be empirically disconfirmed (e.g., by studies of aphasics). There is evidence for a spreading activation along pathways within the mental lexicon that leads to selection among partial matches between meaning and form for the appropriate listeme (Altman, 1990; Levelt, 1993; Aitchison, 2003). There is, of course, nothing to be gained by rewriting desktop dictionaries in terms of networks if they are going to be consulted in the same way human beings have consulted them in the past.

Lhuyd, Edward (ca. 1660–1709)

B F Roberts, Ceredigion, UK

© 2006 Elsevier Ltd. All rights reserved.

The first Celtic scholar in the modern sense, Edward Lhuyd was familiar with all the insular Celtic vernaculars, and it was his systematic analyses of the phonological relationships between them and continental Celtic that justified the use of the term 'Celtic' as a linguistic category. More generally, the theory and methodology that underpin his study of language relationships are significant contributions to European comparative philology.

Edward Lhuyd (or Lhwyd, the Welsh form of his family name Lloyd, which he adopted about 1690), the illegitimate son of Edward Lloyd, last squire of the bankrupt estate of Llanforda, Oswestry, Shropshire, England, and of Bridget Pryse, daughter of a cadet branch of the influential Pryse family of Gogerddan, Cardiganshire, Wales, was born about 1660 and raised in Shropshire where he lived with his father at Llanforda. The Lloyds were an old Oswestry family who had been patrons of poets and harpists and who had played their part in local administration, but none of these activities survived the English Civil Wars (1642–1646, 1650–1651). Edward Lloyd, in spite of his reputation as being both reckless and dissolute, is an interesting example of 17th-century scientific culture. He was an enterprising horticulturalist, carried out his own chemical experiments, and was patron to an experienced professional gardener and field botanist, Edward Morgan. Relationships between father and son were often strained, but Lhuyd regarded the aging Morgan as one of his tutors, and there is no doubt that he took an interest in his father's experiments. Following his father's death, Lhuyd went to Jesus College, Oxford, in 1682 to begin his training in law, but practical botany and related field work, which he had already undertaken in north Wales and around Oswestry, and chemical and other experiments at Llanforda led him to the recently established Ashmolean Museum and to the meetings of the Oxford Philosophical Society. Robert Plot, professor of chemistry and Keeper of the Museum, was sufficiently impressed by the young man's skills and ideas to appoint him as an assistant at the Ashmolean, where, in turn, he became Keeper in 1691. Lhuyd threw himself into the work of the museum – cataloguing library accessions, seeking out new samples to enrich the fossil collections (his catalogue of British 'formed stones' appeared in 1699), and developing his knowledge of flora habitats, especially the Alpine plants of Snowdonia, north Wales, where he discovered *Lloydia serotina*, the

Ælfric (fl. 987–1010)

M Cummings, York University, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Recognized as the greatest Old English prose stylist, Ælfric is also the author of the first grammar in English. In 987 he went as master of novices to the monastery of Cernel (modern Cerne Abbas, Dorset), already in orders, and thus he was at least 30 years of age. He had been a pupil of the reforming Bishop Æthelwold in the school at Winchester. With his contemporary Wulfstan, Archbishop of York (obit. 1023), he was one of the two most prominent literary figures of the Benedictine Reform. His production of the *Catholic Homilies* belongs to the period 990–995, that of the *Lives of Saints* was no later than 998, and he became the first Abbot of Eynsham, near Oxford, in 1005.

His work in language education includes the grammar, a glossary, and the *Colloquy on the Occupations*. The first of these works is the *Excerptiones de arte grammatica anglice*, designed to introduce junior students to the Latin grammar. It is based on the *Excerptiones de Prisciano*, a Latin treatise of the 9th century, compiled from the 6th century *Institutiones grammaticae* of Priscian, and like it concentrates on Latin syllabification, graphology, phonology, parts of speech, and morphology. The *Glossary* is a compilation of Latin vocables with Old English glosses. The *Colloquy* is an imaginary Latin dialogue between a master and his pupils, who represent themselves as having various occupational roles, the ploughman, the huntsman, the fisherman, and so forth. Each describes the habits and rigors of the occupation, sometimes sympathetically.

Ælfric's other extant works include the *Catholic Homilies*; the *Lives of Saints*; a *De temporibus anni*; and a collection of letters, most notably one to the bishop of Sherborne, Wulfsige, and two to Archbishop Wulfstan, designed as expert responses to theological questions. His prose is remarkably lucid in comparison with that of some authors of the period. Parts of his work are rendered in a heightened style that has been called *rhythmic prose*, which in its metrical regularity shares some of the characteristics of Old English verse but is distinct from it. His work has long been taken as the exemplar of the Late West Saxon historical and regional dialect.

The *Catholic Homilies* were produced in two series that together comprise alternate English sermons for Sundays and saints' days. Like the grammar, however, they are based on a Latin exemplar, the late 8th century *Homiliary* of Paul the Deacon, which was created for reading in the monastic offices. The *Lives of Saints* are English versions of lives and martyrdoms for saints celebrated in the monastic liturgy, mainly taken from a 9th century Latin collection. The *De temporibus anni* inculcates the chronology necessary for the calculation of the Easter date.

Affixation

A Carstairs-McCarthy, University of Canterbury, Christchurch, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Definition

An affix is a bound morph that (1) is not a root and (2) is a constituent of a word rather than of a phrase or sentence. Some examples that follow illustrate the implications of (1) and (2). The next section surveys the kinds of affixation that occur, and the last sections discuss theoretical issues.

In most complex words, identifying a root (or roots, if the word is a compound) presents little difficulty. For example, in the words *misfortunes* and *premeditated*, the roots are clearly *fortune* and

Lhuyd, Edward (ca. 1660–1709)

B F Roberts, Ceredigion, UK

© 2006 Elsevier Ltd. All rights reserved.

The first Celtic scholar in the modern sense, Edward Lhuyd was familiar with all the insular Celtic vernaculars, and it was his systematic analyses of the phonological relationships between them and continental Celtic that justified the use of the term 'Celtic' as a linguistic category. More generally, the theory and methodology that underpin his study of language relationships are significant contributions to European comparative philology.

Edward Lhuyd (or Lhwyd, the Welsh form of his family name Lloyd, which he adopted about 1690), the illegitimate son of Edward Lloyd, last squire of the bankrupt estate of Llanforda, Oswestry, Shropshire, England, and of Bridget Pryse, daughter of a cadet branch of the influential Pryse family of Gogerddan, Cardiganshire, Wales, was born about 1660 and raised in Shropshire where he lived with his father at Llanforda. The Lloyds were an old Oswestry family who had been patrons of poets and harpists and who had played their part in local administration, but none of these activities survived the English Civil Wars (1642–1646, 1650–1651). Edward Lloyd, in spite of his reputation as being both reckless and dissolute, is an interesting example of 17th-century scientific culture. He was an enterprising horticulturalist, carried out his own chemical experiments, and was patron to an experienced professional gardener and field botanist, Edward Morgan. Relationships between father and son were often strained, but Lhuyd regarded the aging Morgan as one of his tutors, and there is no doubt that he took an interest in his father's experiments. Following his father's death, Lhuyd went to Jesus College, Oxford, in 1682 to begin his training in law, but practical botany and related field work, which he had already undertaken in north Wales and around Oswestry, and chemical and other experiments at Llanforda led him to the recently established Ashmolean Museum and to the meetings of the Oxford Philosophical Society. Robert Plot, professor of chemistry and Keeper of the Museum, was sufficiently impressed by the young man's skills and ideas to appoint him as an assistant at the Ashmolean, where, in turn, he became Keeper in 1691. Lhuyd threw himself into the work of the museum – cataloguing library accessions, seeking out new samples to enrich the fossil collections (his catalogue of British 'formed stones' appeared in 1699), and developing his knowledge of flora habitats, especially the Alpine plants of Snowdonia, north Wales, where he discovered *Lloydia serotina*, the

'Snowdon lily,' sometime before 1696. Typical of his time, Lhuyd did not draw lines of demarcation between disciplines; he was as interested in antiquities, onomastics, and languages as in paleontology and botany, seeing them all as aspects of history, natural and human. These interests were brought together in 1693 when he was invited to revise the entries on the Welsh counties in Edmund Gibson's new English edition of Camden's *Britannia* (1695). The field work Lhuyd undertook whetted his appetite, and he welcomed an invitation by 'some gentlemen in Glamorganshire' to write a 'British Dictionary, Historical and Geographical . . . and a Natural History of Wales.' He seized the opportunity to undertake an extended tour of 'Celtic Britain' (Wales, the Scottish Highlands, Ireland, Cornwall, and Brittany) from 1697 to 1701 to gather material for an ambitious series of books bearing the general title *Archaeologia Britannica*. The invitation was not fortuitous, as Lhuyd's broadening interests in antiquities and language as a tool for historians were well known. He had already collaborated with John Ray in the latter's *Collection of English words not generally used* (1691) in a discussion on the similarities between some north-country English dialect words and Welsh, a discussion that reveals Lhuyd's familiarity with current linguistic thinking and questions of language contact. He began learning Irish about this time, and linguistic queries were increasingly being put to him. Lhuyd's tour with his four assistants produced a remarkable collection of raw data – samples of flora and fauna, descriptions of parishes, antiquities and customs, collections of literary manuscripts and transcripts, dictionaries and wordlists, and transcriptions of spoken vernacular material. Lhuyd analyzed much of the linguistic data on his return to Oxford in 1701 and in 1707 saw the publication of *Glossography*, volume I of *Archaeologia Britannica*, the only part to appear. He died two years later, in 1709.

The underlying theme of Lhuyd's project was historical, one of his aims being to present a 'Clearer Notion of the first Planters of the Three Kingdoms [Wales was subsumed within the crown of England] and a better understanding of our Ancient Names of Persons and Places.' The language of place-name elements and naming compounds would indicate the peoples responsible for their creation, and knowledge of the 'original' languages of Britain, their inscriptions, and early literatures was a necessary skill for the historian. *Glossography*, therefore, contained grammars of Irish, Breton, and Cornish (Welsh was already catered for) together with dictionaries of Breton, Welsh, and Irish (Lhuyd's Cornish dictionary was set aside in the expectation that another was being prepared, but it remains in manuscript). But even more important than language skills was the recognition that the key to the history lay in the vocabulary of these languages; an analysis of the phonology of words in the cognate 'original' languages would reveal their affinities while borrowings were an indicator of contacts between their speakers. Etymology was already an accepted tool of historical linguistics, but without a rational framework to categorize sound changes, it was prone to deteriorate into meaningless comparisons of superficially similar words in any two or three languages. Lhuyd's major contribution was to reduce the arbitrary element in etymology by formulating criteria for examining and recognizing regular phonetic correspondence and determining what languages might bear valid comparison. These criteria he set out in the opening chapter of *Glossography*, 'Comparative Etymology, or Remarks on the Alteration of Letters.' His guidelines for etymology are reasoned, e.g., identity of signification, declensions, and conjugations are proper to individual languages, old or obsolete words may be found in modern dialects, the words to be compared should be the oldest and most simple, the obvious and necessary. Lhuyd argued that languages develop from a parent by changes in the sense of words, by an accidental transposition of sounds or syllables, by the addition or loss of syllables, by the use of different prefixes or suffixes, by mispronunciation, and by borrowings; and he then worked through a host of examples according to a number of 'observations' summarized under 10 headings, including seven classes of phonetic change. Lhuyd's reasoned analysis of *permutatio litterarum* allowed him to define better than ever before the relationship of Irish, Welsh, and 'Gaulish.' Most of Lhuyd's criteria for language change were phonological; he realized that different orthographical conventions in the various languages could mislead the etymologist. He devised his own phonetic alphabet, a 'general alphabet' to facilitate genuine comparison between languages. In this, as in his methodology of comparative linguistics, Edward Lhuyd was a pioneering forerunner of the Celtic studies and linguistic scholarship of the 19th century.

Li Fang-Kuei (1902–1989)

R J LaPolla, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

Fang-Kuei Li was one of the foremost scholars of Thai and Sino-Tibetan studies and a major contributor to Amerind studies. Born in China, he was one of the early scholars sent to the United States to study. He had developed an interest in language while learning English, Latin, and German as part of his studies in China, and so he decided to study linguistics in the United States. In 1924, he went to the University of Michigan at Ann Arbor, receiving his B.A. 2 years later, then moved to the University of Chicago, where he received his M.A. and Ph.D., studying with Edward Sapir, Leonard Bloomfield, and Carl Darling Buck.

Sapir had the greatest influence on Li. From Sapir he learned phonetics, field methods, and about the languages of Native Americans. Sapir also encouraged Li to read articles on East and Southeast Asian languages. It was Sapir's influence that led Li to take up Thai, Sino-Tibetan and Amerind linguistics. In 1927, Sapir took Li to California to do field work. At first they worked together, but then Sapir sent Li off on his own to work on the Mattole language. There were only two Mattole Indians left at that time, and Li's notes, which he later used as the basis of his Ph.D. dissertation, are the only record of that language.

With Bloomfield, Li studied Germanic linguistics and the methods of text analysis. With Carl Darling Buck, Li studied Indo-European linguistics, especially Greek and Latin. Buck also got Li a fellowship to Harvard in 1928, where Li studied Sanskrit and Tibetan for 6 months. Then, with letters of recommendation from Franz Boas, Li went to Europe to visit linguists there, such as Walter Simon.

After returning to North America in 1929, Li spent 3 months living on an island in the middle of the McKenzie River north of the Arctic Circle doing fieldwork on the Hare language.

On his return to China, he was invited to become a member of the Academia Sinica, where he worked on the Chinese dialects on Hainan Island, and also continued to work on Tibetan.

Li married Ying Hsu in 1932 and later had three children, Lindy, Peter, and Annie.

In 1933, Li went to Thailand to learn Classical Thai, then went to Guangxi to study the Tai languages there. This led to some of his major contributions. Li returned to the United States in 1937 to be a visiting professor at Yale for 2 years, then spent the war years in southwest China, the years 1943–1946 as a visiting professor at the relocated Yanjing University in Chengdu. In 1946, he returned again to the United States, accepting visiting professorships at Harvard, for 2 years, and Yale, for 1 year. In 1949, Li accepted a job at the University of Washington in Seattle and stayed there until he retired in 1969, then accepted an appointment at the University of Hawaii at Manoa, where he stayed until 1974, retiring a second time. Though he retired from teaching, Li continued doing research and publishing. In all he authored nine books and over 100 articles.

In addition to his academic accomplishments, Li was a talented painter in Chinese and Western watercolors. He played the Chinese flute well, and enjoyed singing and teaching Kunqu, the musical drama of the Ming dynasty.

Liberia: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Liberia, one of Africa's oldest republics, has a population of 3 390 635 (July 2004 estimate) over an area of 111 370 sq km. It is located in western Africa, bordering the North Atlantic Ocean, between Ivory Coast and Sierra Leone in a terrain that consists of mostly flat to rolling coastal plains, rising to rolling plateau and low mountains in the northeast. It shares land borders with Guinea (563 km), Ivory Coast (716 km), and Sierra Leone (306 km).

Table 1 Number of speakers according to language

Group	*Language*	*Number of speakers (1991 est.)*
Mel	Gola	99 300
	Kisi	115 000
Mande	Bandi	70 000
	Dan	200 000
	Kpelle	487 400
	Loma	141 800
	Mano	185 000
	Manya	45 400
	Mende	1970
	Vai	89 500
Kru	Bassa	347 600
	Dewoin	8100
	Gbii	5600
	Glaro-Twabo	3900
	Grebo dialects	193 200
	Klao	184 000
	Krahn dialects	47 800
	Kuwaa	12 800
	Sapo	31 600
	Tajuasohn	9600

Although Liberia was founded by freed American slaves, 95% of the population is now composed of indigenous Africans of the ethnic groups Kpelle, Bassa, Gio, Kru, Grebo, Mano, Krahn, Gola, Gbandi, Loma, Kisi, Vai, Dei, Bella, Mandingo, and Mende. The descendants of slaves only make up the remaining 5% of the population, equally divided between the Americo-Liberians (descendants of American slaves) and the Congo People (descendants of Caribbean slaves).

The official language is English, although only 20% of the population speak it. Most Liberians speak one or more of the 29 African languages spoken in the country, a few of which are written and are used in correspondence. All languages of Liberia are Niger-Congo languages, and they belong to one of three groups within that family: Mande, Kru, or Mel (**Table 1**).

Literacy rates have shown great improvement in the last decade, with a total adult literacy of 57.5% in 2003 compared to 25% in 1989. Of this, 73.3% are men and 41.6% women.

Libya: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The Great Socialist People's Libyan Arab Jamahiriya (i.e., 'state ruled by the masses') is a country of 1.77 million square kilometers on the southern Mediterranean coast, in North Africa. More than 90% of the country is desert or semi-desert, and the majority of the population live along the 1750-kilometer-long coastal strip. Libya borders on Tunisia and Algeria in the west, Chad and Niger in the south, and Egypt and Sudan in the west.

The sole official language of Libya is Arabic, and this is also the first language of the large majority of the 5.5 million Libyans. Like many countries in the Arab-speaking world, Libya is in a diglossic situation, in which Modern Standard Arabic (Arabic, Standard), which is used only as a second language, is used in education, in the media, for writing, and in some formal situations, while different Libyan dialects of Arabic are used for daily communication. In the south and in the west of the country, Berber-speaking communities are found, including 140 000 speakers of Nafusi in western Libya and 25 000 Tuaregs, speaking Hoggar and Ghat dialects of Tamahaq (Tamahaq, Tahaggart) (or Tamasheq). Ghadamès, Awjilah, and Sawknah are smaller Berber languages, and the last two may be extinct.

The language of education is Arabic, and literacy in Arabic has significantly increased during the last decade, from 68.1% in 1990 to 81.7% in 2002. However, there is an imbalance between literacy of females (70.7%) and males (91.8%). English is the most widely taught foreign language and is used as a language of instruction in some parts of tertiary education.

Italian, the language of the former colonial power, while still used in business, plays no part in the wider public life, government, or the education system, partly as a result of a strong Arabization program following the revolution in 1969, during which legal decrees ensured that street signs, shop windows, signboards, traffic signs, etc., were written in Arabic.

The media in Libya use Arabic in print and broadcasting. An international edition of *Al-Fajir al-Jadid* is published fortnightly in English, and the external radio service Voice of Africa broadcasts in Arabic, English, and French.

Liechtenstein: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The tiny Principality of Liechtenstein is sandwiched between Austria to the east and Switzerland to the west. The official language of Liechtenstein is German, and it is in fact the only country in the world where German is the only official language. Liechtenstein is in a diglossic situation: while the official language is standard German – including the 1998 spelling reform to which Liechtenstein is party – the spoken language is an Alemannic dialect of German, similar to the German spoken in Switzerland. There is some dialectal variation, and in particular the dialect of Triesenberg stands apart as a distinct conservative variety of Walser Alemannic, whose speakers came to Liechtenstein around 1300 from the western Swiss canton of Wallis.

In addition to the local variety of German, a number of other languages are spoken by foreign residents who comprise more than one-third of the total population (34% of 34 294 in 2003). The majority of foreign residents are from other German-speaking countries, from Switzerland (10.8% of the total population), Austria (5.9%), and Germany (3.4%), and also from Italy (3.3%), countries of the former Republic of Yugoslavia (3.3%), and Turkey (2.6%).

The language of education is German, while Latin, French, English, and Spanish are offered as foreign languages in schools. There are two German-language newspapers, the *Liechtensteiner Vaterland* and the *Liechtensteiner Volksblatt*, and a

Limits of Language

G Priest, University of Melbourne, Melbourne, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

One thing that language (to the sense of which notion we will return in a moment) obviously does well is express things. In particular, it can be used to express information, often of a very complex kind. It might therefore be wondered whether there are limits to this: is there any kind of information that cannot be expressed in language (Alston, 1956)? It is not uncommon to hear it said that there is of course such information: one cannot express the taste of a peach, or the color red. But obviously one ***can*** express such things. The color red is – what else? – red. What is usually meant by inexpressibility claims, say, about redness, is that there is nothing that can be said in words that will conjure up the mental image of red for someone who has never experienced this before. Maybe so. But to identify meaning with such images, though a natural enough view, is hardly tenable. As the 20th-century Austrian philosopher Ludwig Wittgenstein pointed out in the *Philosophical investigations* (Wittgenstein, 1953), there are many words and phrases that conjure up no such images; and if a person is able to use a word correctly in the company of others, what mental images they are experiencing, if, indeed, any at all, is quite immaterial. Their words are meaningful, and so convey their information, in the usual way. (Private images are irrelevant to public meaning.)

It is sometimes claimed that representations such as pictures, maps, and diagrams can convey information that cannot be captured verbally. No doubt they can often express information more effectively, but it is hard to find examples of information expressible only in this way (especially once one has jettisoned the view that mental imagery has any intrinsic connection with meaning). And, in any case, it is natural enough to think of representations of this kind as languages. It seems profitless (to me, anyway) to dispute over whether or not such things *really* are a language. They share with verbal language at least this: they are structured forms of representation that can be used to convey information of a kind that may never have been expressed before. If, therefore, we are looking for information that cannot be represented, we will have to look elsewhere.

It is presumably uncontentious that relative to most – maybe all – systems of representations there will be information that cannot be expressed. Thus, a medieval monk did not have the conceptual resources to speak about microchips and quantum fields. It can still, of course, be represented by some other system – maybe the old one augmented by the appropriate concepts. Similarly, relative to any abstract system of representations, there are likely to be things that can be represented, but that, because of their computational complexity, outstrip the resources available to a human brain, and so are inaccessible. These things could become accessible with the help of a different form of representation, however. (Thus, the multiplication of numbers using Roman numerals is computationally much harder than multiplication using Arabic numerals.) The interesting question is whether there is information that is not just unrepresentable because of contingent constraints of this kind but whether there is information that is essentially so. If there is, it is unlikely that this will be demonstrable without appeal to some substantial metaphysical views.

One such view concerns the nature of God. In certain kinds of Christian theology, God is taken to

radio provider, but most media, and all TV, come from outside Liechtenstein.

Limits of Language

One thing that language (to the sense of which notion we will return in a moment) obviously does well is express things. In particular, it can be used to express information, often of a very complex kind. It might therefore be wondered whether there are limits to this: is there any kind of information that cannot be expressed in language (Alston, 1956)? It is not uncommon to hear it said that there is of course such information: one cannot express the taste of a peach, or the color red. But obviously one ***can*** express such things. The color red is – what else? – red. What is usually meant by inexpressibility claims, say, about redness, is that there is nothing that can be said in words that will conjure up the mental image of red for someone who has never experienced this before. Maybe so. But to identify meaning with such images, though a natural enough view, is hardly tenable. As the 20th-century Austrian philosopher Ludwig Wittgenstein pointed out in the *Philosophical investigations* (Wittgenstein, 1953), there are many words and phrases that conjure up no such images; and if a person is able to use a word correctly in the company of others, what mental images they are experiencing, if, indeed, any at all, is quite immaterial. Their words are meaningful, and so convey their information, in the usual way. (Private images are irrelevant to public meaning.)

It is sometimes claimed that representations such as pictures, maps, and diagrams can convey information that cannot be captured verbally. No doubt they can often express information more effectively, but it is hard to find examples of information expressible only in this way (especially once one has jettisoned the view that mental imagery has any intrinsic connection with meaning). And, in any case, it is natural enough to think of representations of this kind as languages. It seems profitless (to me, anyway) to dispute over whether or not such things *really* are a language. They share with verbal language at least this: they are structured forms of representation that can be used to convey information of a kind that may never have been expressed before. If, therefore, we are looking for information that cannot be represented, we will have to look elsewhere.

It is presumably uncontentious that relative to most – maybe all – systems of representations there will be information that cannot be expressed. Thus, a medieval monk did not have the conceptual resources to speak about microchips and quantum fields. It can still, of course, be represented by some other system – maybe the old one augmented by the appropriate concepts. Similarly, relative to any abstract system of representations, there are likely to be things that can be represented, but that, because of their computational complexity, outstrip the resources available to a human brain, and so are inaccessible. These things could become accessible with the help of a different form of representation, however. (Thus, the multiplication of numbers using Roman numerals is computationally much harder than multiplication using Arabic numerals.) The interesting question is whether there is information that is not just unrepresentable because of contingent constraints of this kind but whether there is information that is essentially so. If there is, it is unlikely that this will be demonstrable without appeal to some substantial metaphysical views.

One such view concerns the nature of God. In certain kinds of Christian theology, God is taken to

be so different in kind from anything that humans can conceive of that no human concepts can be correctly applied to Him. Because all language deploys only such concepts, the true nature of God cannot be expressed in language (Alston, 1998).

The claim that the nature of God is ineffable is sometimes buttressed by other considerations, especially in the Neo-Platonist tradition. God, it is claimed, is the ground of all beings. That is, He is that which creates and sustains all beings. As such, He is not Himself a being: not a *this* rather than a *that*. His nature cannot, therefore, be communicated in words: to say anything about Him would be to say that He is a this, rather than a that, and so treat Him simply as another being.

The thought that beings have a ground of this kind is not restricted to Christianity but seems to be a perennial one. It is found in Neo-Platonism (Christian and non-Christian), in which the One plays this role (O'Meara, 1993); it is found in Hinduism, in which Brahman plays this role; it is found in Taoism, in which the Tao plays this role (Lau, 1982); it is found in the writings of the 20th-century German philosopher Martin Heidegger, in which Being (*Sein*) plays this role (Krell, 1977).

A closely related, but different, view is that there is a fundamental or ultimate reality such that the reality that we perceive or conceive is obtained by the imposition of a conceptual grid thereupon. To say what it is like, in itself, is therefore impossible, as anything said about it will deploy our conceptual grid, which is simply a superposition. Again, the existence of such a reality seems a perennial thought. It is the role played by chora (χωρα) in Plato's *Timaeus;* it is the role played by ultimate reality (emptiness, **śūnyatā**) in various branches of Mahayana Buddhism, especially Yogacara (Williams, 1998). Indeed, when Taoism and Indian Mahayana fused to give Chan (Zen), this theme merged with the previous one. Fundamental reality (Buddha nature) can be appreciated only via a direct experience. It is a simple 'thusness' or 'suchness,' beyond all words (Kasulis, 1989).

In some ways, the views of the 18th-century German philosopher Immanuel Kant, as expressed in his *Critique of pure reason* (Kemp Smith, 1923) are similar. For Kant, the empirical world is not independent of us but is partly constituted by our mental concepts. These include the forms of space and time. More particularly for present concerns, these include the logical categories that we apply when we make judgments (such as *all/some, is/is not*). These categories, moreover, depend for their applicability on temporal criteria. Reason forces us, however, to think (about) reality as it is in itself, independent of our mental constructions 'things in themselves' (*dinge an sich*). And because such things are outside time, there is no way that we can apply our categories to them, and so make judgments about them. Thus, although we are forced to recognize the existence of such a reality, there is nothing that can be said about it.

About a century and a half later, but for quite different reasons, Wittgenstein ended up in a similar situation when he wrote the *Tractatus logico-philosophicus* (Pears and McGuinness, 1961). For Wittgenstein, reality is constituted by certain states of affairs; these are composed of objects configured in certain ways. Language, on the other side of the fence, is constituted by propositions; these are composed of names configured in certain ways. A proposition represents a state of affairs if the names in it correspond to the objects in the state, and the configuration of names in the proposition is isomorphic to (has the same form as) the configuration of objects in the state. (This is the so-called picture theory. Wittgenstein is reputed to have been provoked into it by noting how the icons in a scale-representation work.)

It is a consequence of this view that any situation that is not a configuration of objects cannot be expressed in a proposition. Indeed, attempts to do so will produce semantic nonsense. Such situations cannot, therefore, be described. An irony of this is that Wittgenstein's theory itself requires him to talk, not just of objects but also of propositions, configurations, form; and for various reasons these cannot be objects. (For example, propositions can be asserted or denied; objects cannot. And the form of a state of affairs is not one of the objects in it: it is the way that those objects are structured together.) His own theory is therefore an attempt to do the impossible. This triggers the spectacular dénouement to the *Tractatus,* in which Wittgenstein pronounces his own theory to be nonsense.

The final considerations that I will mention that drive toward things inexpressible concern the infinite, as it is understood in modern logic and mathematics (Moore, 1985). According to this, there are different sizes of infinity. The smallest of these, *countable infinity,* is the size of the natural numbers (0, 1, 2, . . .). Because the totality of objects (or even of numbers) is larger than this, so will be the totality of facts about them. (For each object, for example, it is either finite or infinite.) But any language (at least of the kind that is humanly usable) can be shown to have only countably many sentences. There will therefore be many facts that cannot be expressed.

Of course, for all that this shows, each of these facts could be expressed by some richer language; for example, one obtained by adding another name. But there is more to it than this. To say something

about an object, one has to refer to it; to do this, one has to be able to single it out in some way; and the totality of all objects is so rich that it will contain objects that are entirely indiscriminable from each other by our finite cognitive resources, and so that cannot be singled out. (Points in a continuum, for example, may be so close as to be indistinguishable by any cognitive mechanism.) There is much, therefore, that will be inexpressible.

As we have now seen, there is a wide variety of metaphysical views that deliver the conclusion that there are things that are ineffable. Evaluating these views goes well beyond anything possible here. I will conclude with a brief discussion of a structural feature of (discussions of) the ineffable.

As is probably clear, theories that claim that certain things are inexpressible have a tendency to say just such things. Thus, Christians say much about God, Buddhists say much about emptiness, Heidegger says much about Being, Kant says much about *dinge an sich,* and Wittgenstein says much about the relation between language and reality. What is one to say about this?

The only thing one can say is that these claims are either literally false or meaningless. The second move is made by Wittgenstein in the *Tractatus*. The first move is more common: all one can do is *deny* any claim made about the object in question. One finds this move in Christian negative theology (Braine, 1998) and some versions of Hinduism, for example, the Advaita Vedānta of Śankara (Sengaku Mayeda, 1992). Kant struggles with a version of this view when he distinguishes between a legitimate negative notion of *ding an sich* and an illegitimate positive one.

This cannot be the whole story, however, as each position does appear to endorse various claims about the ineffable. How are these to be understood? The most common move is to suggest that one has to understand such assertions as metaphorical, analogical, or in some other nonliteral way. So understood, they can 'point to' the ineffable, although not express it. In Christian theology, this move is made by the 11th-century theologian St. Anselm; similar claims also can be found in the Zen tradition; and Heidegger uses the notion of writing under erasure ('is') in an attempt to indicate that his words are not to be taken literally.

There is something very unsatisfactory about this, though. One thing that each tradition gives is a set of reasons as to why the thing in question cannot be described: God is beyond categorization; the ground of being is not itself a being; ultimate reality has no features; categories cannot be applied to things outside time; propositions and form are not objects. If one does not understand these claims as literally true, then the very ground for supposing the things in question to be inexpressible falls away. (If 'Juliet is the sun' is not to be taken literally, there is no reason to suppose that she is made of hydrogen and helium.)

Indeed, at the very heart of the view that language has limits is a fundamental paradox (Priest, 1995). To claim that language has limits is to claim that there are things that cannot be talked about; but to say this is exactly to talk about them. The paradox manifests itself in a precise form in some of the paradoxes of self-reference in modern logic. There are many ordinal numbers that cannot be referred to. So there is a least such. But 'the least number that cannot be referred to' refers to that number – Köning's paradox. For skeptics about sizes of infinity, there is even a finite version of this. There is only a finite number of names (i.e., proper names or definite descriptions) with less than (say) 100 letters (in English); there is therefore a finite number of (natural) numbers that can be referred to by names of this kind. So there will be numbers that cannot be referred to in this way. 'The least number that cannot be referred to with less than 100 letters' (which has less than 100 letters) refers to one of these – Berry's paradox. Various responses to these paradoxes have been proposed in modern logic, but none that is either generally accepted or unproblematic.

One reaction to the fundamental paradox is to reject the notion of the limits of language altogether: there is nothing that it is beyond the ability of language to express. But any theory according to which there are limits to language – including, it would seem, contemporary logic – would appear to be stuck with this contradiction.

Linearity/Syntagmatics

There is a group of concepts usually referred to in modern linguistics using the terms linearity and syntagmatics. These concepts are rooted in the beginning of grammatical reflection in classical antiquity, but they emerged explicitly as topics central to linguistic theory with the spread of Saussure's ideas at the beginning of the 20th century. This article discusses linearity and syntagmatics under three headings: (1) in Saussure's *Course in general linguistics*, (2) in syntactic theory, and (3) in the history of grammar.

Linearity and Syntagmatics in Saussure

In Saussure's *Cours de linguistique générale* (Saussure, 1916/1972), there are three areas that refer explicitly to our topic: (1) the linear nature of the signifier, (2) syntagmatic relations, and (3) syntax. These are briefly examined here, giving quotations from Saussure's *Course in general linguistics*, using the English translation by Wade Baskin (Saussure, 1959), which is more literal than in the freer and more sophisticated, but also more eccentric, translation by Roy Harris (Saussure, 1983).

Concerning the first question, the linear character of the signifier, the *Course* (Saussure, 1959: 70) states (Part 1: General principles; Chap. I: Nature of the linguistic sign; Sec. 3, Principle II: The linear nature of the signifier):

> The signifier, being auditory, is unfolded solely in time from which it gets the following characteristics: (a) it represents a span, and (b) the span is measurable in a single dimension; it is a line.

The *Course* adds that, although this principle is obvious, "apparently linguists have always neglected to state it, doubtless because they found it too simple; nevertheless it is fundamental, and its consequences are incalculable." The link between linearity and the time dimension was familiar to Saussure's contemporaries and was repeatedly taken up later in the 20th century. One of the best-known discussions is offered by the valued philosopher of science Hans Reichenbach (1957, 109–110), who stressed the basic difference between time, which is one dimensional, and space, which is, at least at the level of our senses, three dimensional. It would, of course, be desirable to clarify the relation between the single temporal dimension of speech sounds succeeding one another and the single spatial dimension of symbols written one after the other along a line. On the other hand, if the spoken message is inevitably produced and perceived through time, the written message may be perceived as a simultaneous whole, a Gestalt in which different parts are linked by spatial and not temporal relationships.

Concerning syntagmatics, the *Course* states (Part 2: Synchronic linguistics; Chap. 5: Syntagmatic and associative relations; Sec. 2: Syntagmatic relations) that the notion syntagm applies "not only to words but also to groups of words, to complex units of all lengths and types (compounds, derivatives, phrases, whole sentences)." (Saussure, 1959: 124). And later:

> An objection might be raised at this point. The sentence is the ideal type of syntagm. But it belongs to speaking [*elle appartient à la parole*], not to language [*non à la langue*] [. . .] Does it not follow that the syntagm belongs to speaking? I do not think so. Speaking is characterized by freedom of combinations; one must therefore ask whether or not all syntagms are equally free. (Saussure, 1959: 124).

This is followed by a discussion of expressions belonging to *la langue* rather than *la parole*, ending, however, with the caveat (Saussure, 1959: 124–125):

> we must realize that in the syntagm there is no clear-cut boundary between the language fact [*le fait de langue*], which is a sign of collective usage, and the fact that belongs to speaking [*le fait de parole*] and depends on individual freedom.

There is a group of concepts usually referred to in modern linguistics using the terms linearity and syntagmatics. These concepts are rooted in the beginning of grammatical reflection in classical antiquity, but they emerged explicitly as topics central to linguistic theory with the spread of Saussure's ideas at the beginning of the 20th century. This article discusses linearity and syntagmatics under three headings: (1) in Saussure's *Course in general linguistics*, (2) in syntactic theory, and (3) in the history of grammar.

Linearity and Syntagmatics in Saussure

In Saussure's *Cours de linguistique générale* (Saussure, 1916/1972), there are three areas that refer explicitly to our topic: (1) the linear nature of the signifier, (2) syntagmatic relations, and (3) syntax. These are briefly examined here, giving quotations from Saussure's *Course in general linguistics*, using the English translation by Wade Baskin (Saussure, 1959), which is more literal than in the freer and more sophisticated, but also more eccentric, translation by Roy Harris (Saussure, 1983).

Concerning the first question, the linear character of the signifier, the *Course* (Saussure, 1959: 70) states (Part 1: General principles; Chap. I: Nature of the linguistic sign; Sec. 3, Principle II: The linear nature of the signifier):

> The signifier, being auditory, is unfolded solely in time from which it gets the following characteristics: (a) it represents a span, and (b) the span is measurable in a single dimension; it is a line.

The *Course* adds that, although this principle is obvious, "apparently linguists have always neglected to state it, doubtless because they found it too simple; nevertheless it is fundamental, and its consequences are incalculable." The link between linearity and the time dimension was familiar to Saussure's contemporaries and was repeatedly taken up later in the 20th century. One of the best-known discussions is offered by the valued philosopher of science Hans Reichenbach (1957, 109–110), who stressed the basic difference between time, which is one dimensional, and space, which is, at least at the level of our senses, three dimensional. It would, of course, be desirable to clarify the relation between the single temporal dimension of speech sounds succeeding one another and the single spatial dimension of symbols written one after the other along a line. On the other hand, if the spoken message is inevitably produced and perceived through time, the written message may be perceived as a simultaneous whole, a Gestalt in which different parts are linked by spatial and not temporal relationships.

Concerning syntagmatics, the *Course* states (Part 2: Synchronic linguistics; Chap. 5: Syntagmatic and associative relations; Sec. 2: Syntagmatic relations) that the notion syntagm applies "not only to words but also to groups of words, to complex units of all lengths and types (compounds, derivatives, phrases, whole sentences)." (Saussure, 1959: 124). And later:

> An objection might be raised at this point. The sentence is the ideal type of syntagm. But it belongs to speaking [*elle appartient à la parole*], not to language [*non à la langue*] [. . .] Does it not follow that the syntagm belongs to speaking? I do not think so. Speaking is characterized by freedom of combinations; one must therefore ask whether or not all syntagms are equally free. (Saussure, 1959: 124).

This is followed by a discussion of expressions belonging to *la langue* rather than *la parole*, ending, however, with the caveat (Saussure, 1959: 124–125):

> we must realize that in the syntagm there is no clear-cut boundary between the language fact [*le fait de langue*], which is a sign of collective usage, and the fact that belongs to speaking [*le fait de parole*] and depends on individual freedom.

Concerning syntax, the *Course* mentions (Part 2: Synchronic linguistics; Chap. 7: Grammar and its subdivisions; Sec. 1: Definitions: traditional divisions) "the interchange of simple words and phrases within the same language" (Saussure, 1959: 136), for example, *considérer* and *prendre en considération* or *se venger de* and *tirer vengeance de,* which can replace one another.

> Functionally, therefore, the lexical and the syntactical may blend. There is basically no distinction between any word that is not a simple, irreducible unit and a phrase, which is a syntactical fact. The arrangement of the subunits of the word obeys the same fundamental principles as the arrangement of groups of words in phrases. (Saussure, 1959: 136–137)

Later, the *Course* states (Sec. 2: *Rational divisions;* Saussure, 1959: 136–137) that

> syntax (i.e., theory of word groupings, according to the most common definition) goes back to the theory of syntagms [*rentre dans la syntagmatique*], for the groupings always suppose at least two units distributed in space. Not every syntagmatic fact is classed as syntactical, but every syntactical fact belongs to the syntagmatic class [*tous les faits de syntaxe appartiennent à la syntagmatique*].

Earlier on (at the beginning of Chap. 5; Saussure, 1959: 123), the editors of the *Course* had stressed in a footnote: "It is scarcely necessary to point out that the study of *syntagms* is not to be confused with syntax. Syntax is only one part of the study of syntagms."

The paradoxical and contradictory way that these three aspects of Saussurean linguistics (linearity, syntagmatics, and syntax) are treated in the *Course* cannot fail to strike the observer. On the one hand, their importance is explicitly stressed; on the other, they are largely disregarded in the book. Even the relations among these three concepts are presented in a confusing and unclear way that has caused many interpreters of Saussure's ideas to disagree about how they should be properly clarified or to reject some of these assumptions and proposals once their meaning has been established. (See in particular Jakobson's 1939 comments in a lecture given in Copenhagen on the simultaneity of distinctive features, published in Jakobson, 1962: 304–305; Godel, 1957; Engler, 1974; Wunderli, 1981; Amacker, 1995; Lo Cascio, 1995.) The dichotomy between syntagmatic and associative relations has often caused misunderstandings. It is presented as an opposition between *in praesentia* vs. *in absentia* relations, that is, relations between items that are all present in the same syntagm (they are linked by syntagmatic relations) versus relations between items of which only one is present and that is linked to other, absent items by associative (or paradigmatic, as they are generally called, following Hjelmslev, 1961) relations. This constitutes a paradigm, to use Saussure's (1959: 126–127) term:

> Whereas a syntagm immediately suggests an order of succession and a fixed number of elements, terms in an associative family occur neither in fixed numbers nor in a definite order [. . .]. A particular word is like the center of a constellation; it is the point of convergence of an indefinite number of coordinated terms [. . .]. But of the two characteristics of the associative series – indeterminate order and indefinite number – only the first can always be verified; the second may fail to meet the test. This happens in the case of inflectional paradigms, which are typical of associative groupings. Latin *dominus, domini, domino*, etc., is obviously an associative group formed around a common element, the noun theme *domin-*, but the series is not indefinite as in the case of *enseignement, changement*, etc.; the number of cases is definite. Against this, the words have no fixed order of succession, and it is by a purely arbitrary act that the grammarian groups them in one way rather than another.

As a matter of fact, depending on the school tradition, the Latin paradigm is given as *dominus, domini,* and so on or as *dominus, dominum,* and so on.

Linearity and Syntax

One of the most striking features of linguistic theory during the last 50 years is the change from a Saussurean to a Chomskyan perspective. Syntax had a vital part in bringing about this change and, in turn, acquired a different complexion in this process. Chomskyan syntax clearly belongs to *langue* rather than *parole* and resides in the individual's competence rather than being a social fact, to use Saussure's notions. For Chomsky, it was part of i-language and not of e-language.

The traditional view of the spoken chain, or of sentences consisting of strings of words following one another, is obviously misleading. A sentence, spoken or written, consists of constituents, variously called phrases, syntagms, or word groups. Since at least the 18th century, word groups (Graffi, 2001: 136), not individual words, were traditionally considered the building blocks of syntax, that is, to be the basic units entering into grammatical relations with other units or having certain functions, such as subject or object.

A central insight in Chomskyan syntax (Chomsky, 1957) is that grammatical functions (or relations), such as subject and object, are defined, not in terms of meaning (thematic roles or theta roles, such as Agent, Patient etc.), or of the communicative

dynamism of the message (the theme, or topic of which a person is speaking, and the rheme, or comment about it), but in configurational terms, on the basis of the position that a category symbol, such as Noun Phrase (NP), occupies within the tree representing the syntactic structure of the sentence: The subject is the NP that is directly dominated by the node Sentence (S), and the object is the NP that is directly dominated by the node Verb Phrase (VP).

Trees are configurations studied by the branch of topology called graph theory, based on the work of the great Swiss mathematician Leonhard Euler (1707–1783). Traditionally, a sentence was seen as a string of symbols following one another in time or along a single line (hence the expressions linearity and linear word order). But trees, which were introduced into many different disciplines from the beginning of the 19th century, suggested a different image, with branches departing from nodes, and allowed a different graphic representation of syntactic structure, such as that of the phrase markers adopted by generative linguistics.

A tree can be equivalently represented by a string in which category symbols are enclosed in brackets. For the sentence *John hit the boy*, the phrase marker of the tree diagram illustrating the structure of the sentence may appear as the following string:

$[_{S}[_{NP}[_{N}$ John $]_{N}]_{NP}$ $[_{VP}[_{V}$ hit$]_{V}$ $[_{NP}[_{Det}$ the $]_{Det}[_{N}$boy $]_{N}]_{NP}]_{VP}]_{S}$

But this representation is only apparently linear. In fact, the labeled brackets (like the tree) convey the crucial information, not available from the linear word order, that *John*, because it is directly dominated by S, is the subject and that *the boy*, because it is directly dominated by VP, is the object. The sentence is **more** than a string of words. It has a syntactic structure. More information is conveyed by the tree (or the equivalent series of self-embedded brackets) than by the linear order of words following one another along one single dimension, temporal in spoken discourse and spatial in written transcription. (For the formal properties of grammars see Luce *et al.,* 1963; for discussions of linearity in generative grammar, see Vincent, 1979; Corver and van Riemsdijk, 1994; Karimi, 2003.)

Linearity in the History of Grammar

The contrast between the central importance of syntax in Chomskyan linguistics and its modest and peripheral position in a Saussurean perspective should not suggest that syntax is a young discipline with only a few decades of life. In fact, the opposite is true – and the attempts to identify the abstract, invisible structure of grammatical relations or functions behind the superficial, visible layer of word order offer important insights into the history of grammatical notions.

It has been suggested that syntax in the modern sense is a medieval creation (Robins, 1980). In Greek and Roman classical culture, subject, predicate, and object (*hupokeimenon/subiectum, kategoroumenon/praedicatum, antikeimenon/obiectum*) were notions belonging to logic. It was only in medieval times that the grammatical notions of *suppositum* and *appositum* for subject and predicate (i.e., verb, or verb + object) were introduced with Petrus Helias and the French schools of the 12th century (Black, 2001: 70–71, 92–93) As for the terms 'subject' and 'predicate,' and their equivalents in modern European languages, they have a complex and varied history that needs to be studied in detail. One of the major experts in medieval logic, L. M. de Rijk (1980: 230), noted that "word order was viewed as the rendez-vous of grammar and ontology" and pointed out (Rijk, 1967) the curious attempts made by medieval logicians to read referential distinctions into different word orders, in particular the position of a noun before (*a parte ante*) or after the verb (*a parte post*), so that *crudas carnes comedi* 'raw meat I ate' is true even if the meat was well cooked when I ate it because the construction *a parte ante* suggests that it was raw earlier, when I bought it. This does not apply to *comedi crudas carnes* 'I ate raw meat' because the construction *a parte post* requires, for the statement to be true, that the meat was still raw when I ate it (Buridanus, 1977: 59, 67–68; 2001, 877, 886–887).

This is not, of course, the way in which Latin grammar works. But even the humanist who contemptuosly criticized the barbaric Latin of medieval logicians like Buridan, acknowledged that different word orders could correspond to different meanings, for instance in *bibas priusquam edas* 'drink before you eat' versus *edas priusquam bibas* 'eat before you drink.'

It is worth remembering that, unexpectedly for modern readers, classical and Renaissance grammars of Greek and Latin found it difficult to explain accusative and infinitive structures, in which both the subject and the object of an infinitive surface as accusatives. The most important ancient syntactician, the Alexandrian grammarian Apollonius Dyscolus (1981: 185–186), stressed the ambiguity in the *Iliad* (Book 5: 118) of *dos de t'em' andra helein*, which could mean 'grant that I may kill the man' or 'grant that the man may kill me.' The famous Renaissance grammarian Thomas Linacre (1524: Fo.51r) deplored the difficulty of constructions such as *Chremetem percussisse Demeam*, in which the subject and the object are

both in the accusative and we have to decide whether Chremes hit Demea or vice versa. Linacre (1524: Fo.78v, Fo. LXXVIIr) also contrasted *volo discere* 'I want to learn' and *volo te discere* 'I want you to learn' and explained that a Hellenism is introduced when we read of Catullus's *phaselus* 'vessel' that it *ait fuisse navium celerrimus* 'says it was the fastest of ships,' with a nominative instead of an accusative. Similarly Sanctius (Francisco Sánchez) in his *Minerva* (Sanctius, 1587: 134v) alleged that *cupio esse dives* 'I want to be rich,' with *dives* in the nominative, is the Greek-style expression, whereas (according to him) the Latin expression should be *cupio esse divitem*.

Linacre (1524: Fo. 50r) distinguished two kinds (*genera*) of construction, the *iustum* 'normal' and the *figuratum* 'figurative.' They differ mainly in word order. And it is striking that some of the most insightful discussions of syntax in the Italian Renaissance are offered by treatises not of grammar but of rhetoric (Lepschy, 2004). This contrast between normal and figurative constructions finds its place within the complex history, which still waits to be properly illustrated, of the distinction between natural and artificial order (*ordo naturalis* and *ordo artificialis*) (Scaglione, 1972; Weijers, 1994: 59–82; Black, 2001: 281; Rizzo, 2002: 198). In the tradition of Latin school teaching, we meet the expression *ordo constructionis*, *ordo verborum*, or just *ordo*. This term, now largely forgotten, has its own entry in the *Oxford English Dictionary*: "In old Latin School-books (*ordo verborum*). The arrangement of words required in translating into English." The *ordo* changed the Latin word order (*ordo artificialis*), preserving the original Latin forms but rearranging them according to English syntax (*ordo naturalis*), and, in doing so, provided the reader with the (syntactic, if not lexical) meaning of the passage. This process throws light, from an unexpected angle, on the distinction, mentioned at the beginning, between linear word order and syntactic structure.

Lingua Francas as Second Languages

C Meierkord, University of Erfurt, Erfurt, Germany

© 2006 Elsevier Ltd. All rights reserved.

In 1953, UNESCO defined a lingua franca as "a language which is used habitually by people whose mother tongues are different in order to facilitate communication between them." Although a number of attempts were made to introduce an engineered lingua franca, such as Esperanto, to achieve such a facilitation for worldwide communication, the languages used as lingua francas today are largely natural languages. Some of these languages are, or were, used worldwide, notably English. Others, such as Arabic, French, Spanish, and Russian, are employed for international communication in a particular geographic area. Thus, Arabic serves as a lingua franca in the states of the Maghreb and the Middle East, Spanish is the major lingua franca of Central and South America, and Russian linguistically united the Soviet Union. In addition, there are languages that are used as intranational lingua francas only. Afrikaans, for instance, is used in large parts of South Africa and Namibia to allow for communication among speakers who do not share another language. Similarly, Modern Chinese is employed for communication across the individual speech communities in the People's Republic of China. In addition, of course, numerous other languages serve groups of different sizes as lingua francas (Languages of Wider Communication).

All of the lingua francas mentioned above have native speaker speech communities. However, they are second languages for the majority of their users, and this has implications both for the individual who uses more than one language as well as for those societies in which several languages coexist. This article considers both the multilingual societies in which lingua francas are used and the bilingual individual using the language. The first part covers aspects such as multilingualism, diglossia, and language shift, and their effects on education and language policy. In the second part, the use of a lingua franca will be discussed as a case of language contact, which involves transfer, borrowing, and code-switching, nativization processes, and similarities with learner languages. The later sections are devoted to a description of lingua franca communication at the international level and a review of approaches toward lingua francas from within the field of foreign language teaching. The article closes with a brief look into current research trends.

Lingua Francas and Multilingual Societies

Lingua francas are used for different purposes. Communication among speakers of mutually unintelligible languages occurs across countries as well as within them. This section will examine lingua francas used for intranational, intraregional, and international communication. It draws on data available for

In 1953, UNESCO defined a lingua franca as "a language which is used habitually by people whose mother tongues are different in order to facilitate communication between them." Although a number of attempts were made to introduce an engineered lingua franca, such as Esperanto, to achieve such a facilitation for worldwide communication, the languages used as lingua francas today are largely natural languages. Some of these languages are, or were, used worldwide, notably English. Others, such as Arabic, French, Spanish, and Russian, are employed for international communication in a particular geographic area. Thus, Arabic serves as a lingua franca in the states of the Maghreb and the Middle East, Spanish is the major lingua franca of Central and South America, and Russian linguistically united the Soviet Union. In addition, there are languages that are used as intranational lingua francas only. Afrikaans, for instance, is used in large parts of South Africa and Namibia to allow for communication among speakers who do not share another language. Similarly, Modern Chinese is employed for communication across the individual speech communities in the People's Republic of China. In addition, of course, numerous other languages serve groups of different sizes as lingua francas (Languages of Wider Communication).

All of the lingua francas mentioned above have native speaker speech communities. However, they are second languages for the majority of their users, and this has implications both for the individual who uses more than one language as well as for those societies in which several languages coexist. This article considers both the multilingual societies in which lingua francas are used and the bilingual individual using the language. The first part covers aspects such as multilingualism, diglossia, and language shift, and their effects on education and language policy. In the second part, the use of a lingua franca will be discussed as a case of language contact, which involves transfer, borrowing, and code-switching, nativization processes, and similarities with learner languages. The later sections are devoted to a description of lingua franca communication at the international level and a review of approaches toward lingua francas from within the field of foreign language teaching. The article closes with a brief look into current research trends.

Lingua Francas and Multilingual Societies

Lingua francas are used for different purposes. Communication among speakers of mutually unintelligible languages occurs across countries as well as within them. This section will examine lingua francas used for intranational, intraregional, and international communication. It draws on data available for

Table 1 Second language speakers of individual lingua francas

Spanish	59

All figures are taken from the Ethnologue at www.ethnologue.org.

Afrikaans, Standard Arabic, Mandarin Chinese, English, French, Russian, and Spanish. Table 1 presents the figures which have been estimated for the numbers of second language users of these languages.

When a language has come to be used as a lingua franca, it is frequently assigned the status of a national or official language of individual countries as documented in Table 2. More detailed descriptions of the linguistic situation and the status of the lingua francas in these countries are available from the Ethnologue (Ethnologue) or from Baker and Prys Jones (1998).

Table 1 and Table 2 indicate that lingua francas are used in different contexts: several languages, such as Arabic, English, French, and Spanish have achieved a special status within a large number of individual countries. Others, such as Afrikaans, Chinese, and Russian, have high numbers of second language users but are used in few countries. The following subchapters provide an overview of the diverse scenarios in which a lingua franca may be encountered, followed by a discussion of the implications its use has at the societal level.

Scenarios of Lingua Franca Usage

Spanish in the Americas and French in Africa As a result of colonization, both Spanish and French are used on a worldwide scale, but they mainly serve restricted geographical areas. Spanish as a lingua franca is mainly used in the Americas, from California as far as Feuerland. Here, Spanish is spoken by a total of approximately 330 million people (cf. Noll, 2001). Most of the second language speakers of Spanish in this area are descendants of Native Americans. However, Native American languages, such as Aravak, Caribe, Nahautl, Maya, Chibcha, Quechua, Arimara, Mapuche, and Guaraní, continue to play a prominent role only in Mexico, Guatemala, the Andes, and Paraguay. In other countries, the majority of their inhabitants have shifted to Spanish as their first language. Cuba and the Dominican Republic have predominantly Black populations. Here, Spanish speakers are mainly descendants of the formerly enslaved African peoples and the European colonizers.

The francophone world covers large parts of Europe, America, and Africa. French has the status of a lingua franca in many sub-saharan countries, such as the Ivory Coast, countries in the Indian Ocean, the states of the Maghreb, Andorra, Luxemburg, the Aosta Valley, Vanuatu, Lebanon, etc. (cf. Kleineidam, 1992). More than half of all francophones live in Africa. But different from the case with Spanish in Latin America, French is not spoken by the vast majority of these countries' inhabitants. In fact, French is often accessible only to a middle class elite. However, Kleineidam (1992) documents that figures for second language speakers of French have been steadily rising between 1980 and 2000 in Africa: there was an increase of 267% in sub-Saharan Africa and of 160% in the Maghreb states.

Arabic is used inside as well as across more than twenty countries, mainly located in the Middle East and northern Africa. In these countries, Modern Standard Arabic fulfills the function of an official language, as the medium of education and administration, and for all written communication. In addition, all Muslim states are unified through the literary and written standard provided by Classical Arabic, the language of the Islamic religion and of the Qur'ān (cf. Youssi, 1995).

Intranational Lingua Francas: Afrikaans, Russian, and Chinese Whenever the political frontiers of a nation were drawn regardless of ethnolinguistic realities, the country is frequently inhabited by speakers of diverse languages. Such multilingual states often decide on one particular language for intranational communication across their different speech

Table 2 Lingua francas enjoying a special status

Language (L)	*Number of countries in which L is spoken*	*Number of countries in which L is a national language*	*Number of countries in which L is an official language*	*Number of countries in which L enjoys a special status*

Russian	31	–	1	2
Spanish	44	19	1	4

communities. This is – or was – the case, for example, in China, the former Soviet Union, and South Africa.

In China, which officially recognizes 56 nationalities and 125 minority languages (cf. e.g., Sun, 2001 cited in Poa and LaPolla, forthcoming), Mandarin Chinese – also called Modern Standard Chinese or *pǔtōnghuà* – is the sole official language. It was formally defined and standardized after World War II and became the medium of instruction in schools, the working language for government and administration, and the language of the media (cf. Chen, 1999: 27). Stern measures to implement Modern Standard Chinese were never adopted in mainland China. Rather, migration of people across the empire has been encouraged, if not enforced, by the government. As a result, bilingualism in Mandarin Chinese and a local variety is the norm in large parts of China today. In 1984, 50% of the whole nation had a speaking proficiency in Modern Standard Chinese, and 90% had a comprehension proficiency in the language.

Strategies were similar in the former Soviet Union, which contained peoples speaking more than 130 different languages, but where the government never installed Russian as the national language. Instead, Russian was introduced as a compulsory school subject and promoted as a key to being a full Soviet citizen, based on the "Marxist principle that at some time in the future all ethnic groups will fuse into one" (Comrie, 1981: 37). Social planners supported migration of Russians into remote regions of the state, producing multilingual communities and mixed marriages, mostly with Russian as the dominant language. In 1979, a total of 61.2 million speakers of Russian as an additional language lived in the Soviet states, and the federation was characterized by frequent instances of bilingualism, such as Estonian-Russian, Armenian-Russian, etc. (cf. Haarmann, 1985).

A language that has been vigorously enforced as an intranational lingua franca is Afrikaans. Afrikaans was designated as the national language when the Afrikaner Nationalist Party came into power in 1948. Partly in response to the former aggressive anglicization policy effected by the British, Afrikaans was promoted and made the compulsory language of instruction in all Black schools in 1957. Following the abolition of the apartheid policy, Afrikaans is now one of eleven official languages, but due to its background it still is a major lingua franca in South Africa and parts of Namibia. The language has been a lingua franca from when it developed in a sustained situation of language contact between the indigenous Khoekhoe, Dutch settlers, and slaves (cf. McCormick, 2002). It is spoken widely in large parts of South Africa, both as a first and as a second language, by speakers from a variety of ethnicities.

Global Lingua Francas: English Among the different lingua francas which exist around the world, English is the language which has gained the status of a global language. It is used for worldwide communication across nations and individuals, who speak mutually unintelligible languages, but it also serves as an intranational lingua franca in a large number of countries which had previously been colonized by the British (cf. Table 2).

The dominance of English at the international level has sometimes been discussed as linguistic imperialism. Phillipson and Skutnabb-Kangas (2001: 573) argue that "a Western-dominated globalization agenda is being implemented by the transnational corporations, the World Bank, the IMF, and the World Trade Organization." The status of English is strengthened through these global alliances but also through organizations that operate at a regional level. Moreover, increased global mobility, migration, and modern media help the spread of English today. As a result, English has gained enormous prestige, and mastering the language is associated with access to the global market. Crystal (1997) estimates that approximately 1000 million people speak English as a second language today, albeit at different levels of competence.

Societal Effects of Lingua Franca Usage

Languages used as intranational lingua francas frequently have the status of a national or official language and are used for governmental and administrative affairs. Raising the status of one of several languages spoken in a country eventually results in the language being more prestigious and associated with professional success and upward social mobility. These often diglossic situations have an impact on education and may eventually cause language shift.

Diglossia Frequently, the two or more languages used within one nation coexist in a diglossic situation (Fishman, 1980): One language is used for 'high' functions, i.e., in formal interactions such as official discourse, in church and schools, and especially in written communication. The other language is used for so-called 'low' functions: informal, mundane, mainly oral interactions. As a result, the high language is often held to be more logical and aesthetic, associated with literary heritage, and it is also the one which is acquired through formal education. For example, Modern Standard Arabic is used in most formal contexts in the Maghreb states, and a colloquial variety of Arabic, or Berber in the case of for example Morocco, is used in informal, oral situations. In Paraguay, where Spanish and Guaraní are the two official languages, Spanish performs the high functions.

Educational Issues The prestige of a lingua franca performing high functions in a country may also influence language policy, and there may be parental or societal demand that the lingua franca be used as the medium of instruction in schools or taught at the expense of other languages. Such is the case for example in South Africa, where English is now increasingly used as a medium of instruction in schools where neither the pupils nor the teachers speak English as their mother tongue. However, designating a lingua franca as the sole or major medium of instruction may have severe consequences for pupils' social, cognitive, and academic development. Desai (2003) documents that Xhosa children who receive their primary school education through English do not only fail to acquire English effectively, but that they also do not develop proficiency, especially in reading comprehension, in their mother tongue. Also, using the lingua franca may exclude those sections of the population who do not have access to it from socioeconomic advancement. In some cases, the language used as lingua franca may be completely inaccessible to certain groups of society, yielding a bilingual or multilingual elite. For example, several rural areas of China are still without electricity, and access to schools is also limited in some cases, so that as a result citizens have no opportunity to acquire *pǔtōnghuà* through the media or in school.

Even if the lingua franca is not used intranationally, such as English in Germany, individuals may prefer to study this language rather than another foreign language if it is more prestigious and required for the more attractive professions. In fact, Europe today witnesses an enormous increase in English language learning, often to the detriment of multilingualism.

Language Shift When proficiency in the lingua franca is a prerequisite to professional and social achievement, language shift is also likely to occur, i.e., bilingual communities will tend to give up their original mother tongue and gradually, usually over three generations, acquire a new language. In South Africa, Indians gradually shifted to English (cf. Mesthrie, 1992), and at present, Blacks increasingly raise their children in English instead of Afrikaans, because English seems to guarantee upward societal movement (cf. McCormick, 2002). Haarmann (1992: 111) points out that following a phase of unbalanced bilingualism with Russian as the dominant language, "by 1979 about 16.3 million non-Russians (such as Ukrainians, Latvians, Georgians) had shifted to Russian as their first language." And in China, the Qiang have been undergoing language shift to the dominant *pǔtōnghuà* due to a lack of literature, media, and education in Qiang and the rapid increase in Chinese-Qiang bilingualism. The process of language shift is, however, not always completed. The Black community in Cape Town, South Africa, on which McCormick (2002) reports, uses English in education and at the workplace. However, the individuals in this community still enact their identities in a mixed Afrikaans-English code.

Lingua Francas and the Multilingual Individual

The wide range of social contexts in which lingua francas are used is reflected in the heterogeneity of the forms which languages assume when they are used as lingua francas. Depending on the presence and status of the lingua franca in a particular country, speakers acquire and use the language differently. Speakers living in nations that utilize a lingua franca for intranational purposes frequently acquire a nativized variety of the lingua franca. But in countries where the lingua franca does not enjoy a particular official status and where it is mainly acquired for communication with interlocutors from abroad, the model has usually been either British English (in Europe) or the American Standard variety (e.g., in Japan). Interestingly, Korea has adopted a strategy of teaching a variety called Codified Korean English.

Furthermore, the environment in which a lingua franca is acquired varies considerably. Lingua francas are usually taught as second languages in institutional settings. But they are also present in everyday life: in official documents, on television and on the radio, in advertisements etc. These different options for contact with the lingua franca yield diverging opportunities for either instructed or informal acquisition of the language.

Formal and Natural Acquisition of Lingua Francas

In many cases, a lingua franca is learned in an institutionalized context. This is the case whenever the language is not used intranationally. For example, English is a subject in Germany, Italy, Turkey, Japan, and many other countries. If a language is used as an intranational lingua franca, it is often still acquired in an institutionalized context. Thus, mother tongue speakers of Xhosa or Zulu in South Africa learn English from primary school onward. At the same time, however, the lingua franca is usually used in several public domains, especially in the media, and speakers may simultaneously acquire it naturally so that formal instruction and natural acquisition supplement each other. This is the case for example in China, where Modern Standard Chinese is not only taught and used as the medium of instruction in

schools, but is also the language of access to modern media. Radio and television exposes even very young children to Modern Standard Chinese, which thus becomes part of their local context.

But despite the availability of formal instruction in the languages used as lingua francas, for a large number of their speakers, especially for those who do *not* have access to formal education, acquisition through uninstructed channels is frequently their sole option. They pick up the language in everyday interaction with either native or nonnative speakers, and learning results from direct participation and observation. Although such informal settings potentially create rich language learning environments with a vast array of communicative events, they also leave the learner with the task of constructing the correct rules from the input they receive.

Acquiring the lingua franca in contexts such as the workplace, and without additional instructed learning, may produce errors that remain uncorrected so that nontarget forms eventually become fixed and fossilize. As a result, the speakers achieve a variety of levels of competence, and large numbers will only be able to master a basilectal form of the lingua franca. This is the case in the following sequence, which has been observed with a South African Xhosa speaker who acquired English mainly through interaction with other nonnative speakers.

> my child is in Johannesburg but he's working sometimes wor – not working. I don't know\ another one's three, three years here. and then uh, lady's has got as a house, in Khayelitsha. working in factory to sewing, everything. oh sorry. and another, the lastborn, my lastborn, is in working, he's passed his standard ten last of last year. but he's working now. it's better but eh. all the children is got a problem. because it is not help her parents. you know/

A similar situation characterizes parts of Latin and South America. Lipski (1994: 143) points out, that in Latin America "radio is often the only means of communication for vast rural areas, and for large segments of the population who suffer partial or total illiteracy." Radio stations in these areas provide a medium for adult education and Spanish language classes for the indigenous communities. However, the model that speakers encounter on the radio is heterogeneous in that most broadcasters do not receive training due to a lack of financial resources.

Nativized and Interlanguage Forms of Lingua Francas

When the lingua franca is regularly used for intranational communication, it frequently develops into a nativized form. Transfers from the speakers' mother tongues, which occur at the different linguistic levels, eventually stabilize, and the language is adapted to a new sociocultural context, a process which affects both cultural and formal dimensions. This is most apparent in the lexicon of these varieties. For example, speakers of English in Nigeria have coined the expression *head-tie* to denote a piece of cloth worn around the head by the women in the country. For English, the individual indigenized varieties spoken throughout the world have been thoroughly documented in a vast number of publications, e.g., by McArthur (2002) and especially in the papers published from within the International Corpus of English (ICE) project. With regard to Spanish, sociolinguistic research on Latin America has established that "Latin American Spanish exhibits numerous supraregional characteristics, and a well-defined if unofficial prestige norm valid across two continents" (Lipski, 1994: 149). Instead of being an imitation of Castilian, the Latin American prestige form "is a set of common denominators in which regionally or ethnically marked items do not appear" (Lipski, 1994: 149).

If learning the lingua franca takes place in the classroom context only, speakers' productions frequently display structures and strategies that differ from both the mother tongue and the second language. These interlanguages are approximative, transitional systems, which reflect the developmental stage of the individual learner. They are both unstable and variable, and they are furthermore characterized by communication strategies, employed to compensate for deficits in the second language. For example, paraphrases are used to express lexical concepts for which the interlanguage does not yet contain a specific lexical item. Also, pauses occur frequently between and also within turns, possibly because learners pause to solve production problems. But long pauses that occur between turns may also result from the speakers' reliance on pauses as turn-taking-signals, which implies that they don't sufficiently recognize and produce other turn-taking-signals. Learners have also been shown to display a low variation in ritual speech acts, which seems to be a further classroom- or textbook-induced characteristic. Pöll (1998: 108) documents that speakers of French as a lingua franca in sub-Saharan Africa frequently produce utterances in which individual structures of the French language have been simplified (e.g., *dans* is used as the sole locative preposition in Senegal). Also, concord rules may be violated, as is the case in *les filles ne fait plus ça* (observed in Cameroon).

Linguistic Processes in Lingua Francas Productions

Individuals using a language as a lingua franca by definition command more than one language. As a result of such language contact, the speech of bilinguals using interlanguage varieties as well as nativized forms of individual languages is commonly characterized by borrowing, transfer, code switching, and code mixing.

Borrowing and transfer In present-day Bolivian Spanish, contact with the diverse Native American languages is reflected in the form of lexical borrowings from the indigenous languages Aymara, Chiquitana, Guaraní, and Quechua. For example *apallar* 'to harvest' (cf. Lipski, 1994: 194) or-*cosa!*, an exclamation meaning 'very good, excellent,' have both been copied into Bolivian Spanish. In the diglossic context of Paraguay, borrowing from Guaraní is particularly noticeable. Items for flora, fauna, food, etc., are often of Guaraní origin. For example, *mitaí* is used for 'child' instead of *niño/niña*.

Also, the lingua francas display evidence of transfer in that structures of the indigenous languages influence the speakers' productions in the lingua franca. In Peru, Spanish reflects transfer from Quechua in that the clitic pronoun system has been morphologically simplified, and Quechua word order and tenses have been retained in Spanish (cf. Klee, 1996). Transfer does not, however, radically change the syntactic structure of Spanish. Rather "speakers of Andean Spanish have found a way to maintain the word order patterns and evidential system of Quechua in a manner that is compatible with the pragmatic use and structure of Spanish" (Klee, 1996: 89).

Code Switching and Code Mixing Lingua franca speakers have also been found to mix the indigenous language and the lingua franca into a hybrid consisting of words and phrases of both languages (code mixing). The intrasentential use of two languages seems to be a universally accounted phenomenon in the productions of second language speakers in multilingual settings.

> *ka fa izy edy izany*/ça semble lourd quand c'est en malgache/vous voyez (Babault, 2001: 137; Malegasy in italics).

> Estamos haciendo pruebas, y *tlamis tikisaske* recreo *iwa tlamis tikalakiske oksepa, tlamis* de nuevo vamos a estudiar (MacSwann, 1999: 136; Nahuatl in italics).

But code switching may also occur intersententially, i.e., speakers also change codes between utterances within one speech event. Often, especially in diglossic situations, this is done for stylistic purposes, or due to alterations in the formality of the speech event. The following excerpt taken from McCormick (2002: 168) demonstrates a switch from English to Afrikaans, which does not usually serve formal functions in the community she studied. When speaker 1 becomes uncertain about the date of the next meeting, speakers switch into Afrikaans for a more informal discussion. The conversation changes back to English when the formal reading of the minutes is resumed (Afrikaans in italics).

Speaker 1: The matter could only be entertained when our next AGM elections would be held the chairman closed the meeting and told the members that on Wednesday ninth
Speaker 2: seventeen
Speaker 3: sixteenth
Speaker 4: *laas week was die sestien en die week tevore was die laaste* meeting
Speaker 5: *nee man hy praat van die sestiende* sixteenth May
Speaker 1: (resumes reading the minutes) The chairman closed the meeting and told the members that on Wednesday sixteenth May nineteen eighty four there would be no meeting

McCormick also documents that code switching and code mixing may evolve into a mixed language, which can develop into a marker of identity.

International Lingua Franca Interactions

At the international level, interaction in a lingua franca often implies communication between speakers of different varieties of the lingua franca: indigenized forms and nonnative or learner varieties potentially meet, and as a result interactions in a lingua franca are highly heterogeneous. Lingua franca communication (LFC) implies interaction between various linguistic and cultural systems. Consequently, LFC has been approached from different perspectives: some authors have discussed LFC as a particular type of intercultural communication, whereas others have placed their emphasis on aspects related to interlanguage communication (cf. Meierkord and Knapp, 2002 for a more comprehensive overview).

As a form of intercultural communication, LFC has been conceived as interaction between participants from different cultures or discourse systems. Based on the assumption that speakers in LFC would not share a sufficient amount of shared signs and their conventionalized representations to allow them to

interpret each others' utterances successfully, LFC has often been approached as being potentially problematic. Participants in LFC have been assumed to misinterpret silences, tone of voice, expressions for speech act functions, etc. Several scholars have assumed that interferences from the individual mother tongue will result in more frequent and also more complex problems, if speakers need to resort to a language neither of them speaks as her/his mother tongue. Such interferences may occur "in the types of communicative events that learners expect to occur in a given situation, the manner of their participation in them, the specific types of acts they perform and the ways they realize them, the ways topics are nominated and developed, and the way discourse is regulated" (Ellis, 1994: 187). In fact, early studies carried out in the learner languages paradigm, such as Schwarz (1980) and Varonis and Gass (1985), who investigated the negotiation of meaning between non-native speakers of English with different linguistic backgrounds, discovered such problematic issues.

A number of studies describe the formal properties which English assumes in lingua franca communication. The vast bulk of these studies concentrates on the discourse level. Firth (1996) challenges the above view and argues that participants in lingua franca interactions strive to make interaction 'normal' in the sense that misunderstandings tend to be negotiated following a 'let it pass' attitude. Speakers seem to accept that understanding may be impaired to a certain extent, and they allow for a certain amount of opacity to make the interaction less vulnerable. However, others have documented frequent instances of misunderstanding in the data they elicited (cf. the papers in Knapp and Meierkord, 2002) and have even held that mutual understanding in LFC is a myth (House, 1999).

Descriptive studies investigating the other linguistic levels are still scarce. Meierkord (2004) presents analyses of the syntax in interactions across international Englishes, which reveal an overwhelming similarity of the lingua franca productions with those commonly found in native speaker varieties of English. Particular features, which have been documented for New Englishes or learner varieties, also occur but are infrequent. On the whole, the interactions are characterized by processes of leveling and regularization.

Lingua Francas and Second Language Teaching

The status which English enjoys as a global lingua franca and the variability of the forms which English today assumes have also concerned scholars in the field of English language teaching. The issue had been at the center of discussions in the 1980s, and it has recently gained renewed attention. In the early papers addressing the need for a reorientation of English language teaching, authors suggested that most learners of English would employ the language mainly for communication with other nonnative speakers. Against this assumption, they argued that basing foreign language teaching on a native-speaker model was doubtful and problematic, because it did not sufficiently prepare learners for using the foreign language as a lingua franca. Hüllen (1982: 87) concludes that "[...] the linguistic norms – grammatical, lexical, but also those of pronunciation – will have to change. It is also certain that new means of linguistic politeness and agreed-upon roles in communication will arise." Like him, other authors concentrated on the sociopragmatics of English for international communication and on the negotiation of meaning, both based on the assumption that crosscultural differences in these areas are likely to cause problematic interaction.

A number of authors have also attempted to model a form of English that would be easier to learn than the ones based on the native speaker varieties, yet be communicatively adequate. Ogden's (1933) *Basic English* is one of the earliest proposals for such a variety. It combines a restricted set of grammatical rules with a lexicon of approximately 850 words. Quirk (1985) proposed *Nuclear English*, a form of English characterized by, among other things, a reduction of homosemy, of the complexity of for example restrictive relative clauses and of the system of modal verbs.

Many other authors did not perceive a need to design a particular variety of English as an international lingua franca. For example, Smith (1984) and Crystal (1997) assume that English will develop without the active intervention of linguistic engineers. Smith (1984: 55) assumes that the term *English as an International Language* refers to the different *uses* of the language only, that individual users will employ a number of different forms of English, e.g., nativized varieties, and that participants using English as a lingua franca will need to cope with the resulting heterogeneity. Crystal (1997: 136 ff.) proposes that a form which he calls *World Standard Spoken English* would arise, a form that would coexist with other varieties. Crystal conceives this form of English as characterized by "careful pronunciation, conventional grammar, and standard vocabulary" (Crystal, 1997: 137) and as a variety which "takes the form, for example, of consciously avoiding a phrase that you know is not likely to be understood outside your own country" (Crystal, 137 ff.).

But on the contrary, Burger (2000: 10ff.) attempts to embrace current research findings and proposes the following: a revision of the native speaker as a model

for English language teaching, an acceptance of hybrid learner varieties, a dominance of communicativity over correctness, an increased coverage of second language varieties of English, an inclusion of nonnative varieties in listening training, stressing intelligibility of pronunciation over native speaker acceptance, the training of negotiation of meaning, and activities to raise intercultural awareness.

Outlook: Current Research Trends

Scholars have started to investigate lingua francas from a corpus linguistic perspective. Jenkins (2000) searched her corpus of genuine lingua franca English conversations for instances of native and nonnative speaker pronunciation leading to unintelligibility and misunderstanding. Based on her findings, she argues that a number of sounds, suprasegmentals, and articulatory settings could be modified in comparison to the British or General American English model. In her proposal of what she calls the *Lingua Franca Core*, for example, /θ/ and /ð/ could easily be replaced by /t/ and /d/ or /s/ and /z/ without impeding intelligibility. Similarly, the dark /l/ might be substituted by /ʊ/.

A number of projects that aim at the compilation of corpora of LFC are under way. At the universities of Berne, Basle, and Fribourg, Watts, Allerton, and Trudgill, respectively, look into what they have labeled *Pan Swiss English*, a form of nonnative English emerging among native speakers of Swiss German, French, and Italian in Switzerland. In Austria, Seidlhofer has initiated the compilation of a corpus of *English as a lingua franca* at the University of Vienna (Seidlhofer, 2004; http://www.univie.ac.at/voice/). Mauranen collects data for *English as an academic lingua franca* at the University of Tampere. A slightly different perspective is offered by Meierkord, who relates the findings yielded by the analyses of her corpus of *English as a lingua franca in South Africa* to identity construction in contemporary South African society.

Linguistic Anthropology

S Gal, University of Chicago, Chicago, USA

© 2006 Elsevier Ltd. All rights reserved.

Linguistic anthropology is the study of language **in** culture and society. The field analyzes linguistic practices as culturally significant **actions** that constitute social life. The situated use of language is exemplary of the meaning-making process that shapes a social worlds saturated with contrasting values and contested interests, with opposed political positions and identities, with variable access to institutions, resources and power. Linguistic anthropology examines the role of social interaction – and the semiotic processes on which it relies – in making, mediating and authorizing those contrasts and differences. Aspects of context enter into this process through linguistic form itself, as form signals speaker alignments and cultural presuppositions that are called into play during social interaction. Presuppositions invoked during interaction can draw on any cultural realm: categories of contrasting identities, folk ontologies, notions of truth, space, time, cosmological order, and morality. Such presuppositions are invariably linked to language ideologies, that is, culturally specific conceptions about language and its role in social life.

Recent research on language-in-context has resulted in new definitions of the field's fundamental concepts: 'language' 'metalanguage' 'discourse' 'context' 'event' and 'text.' Metalanguage is crucial because it makes possible the reflexivity that is a necessary feature of verbal interaction. Reflexivity has methodological as well as theoretical implications. Speakers' categories of speech, events and personae are reflexive in that they create frames of interpretation for social interaction and are not necessarily uniform within any group. They are indispensable starting points for empirical investigation of talk. Such categories provide perspectival views on interaction and contrast with the linguists' own perspectives and direct observations. Scholarly discourses and debates about language are of theoretical interest as well. Like the metadiscursive categories about language and interaction of ordinary speakers, expert debates also create frames of interpretation; they participate in cultural systems, and often legitimate relations of power.

In concert with some poststructuralist philosophies, yet in quite different ways, linguistic anthropology analyzes linguistic practices not only as the instruments of social life, but rather as the **ground** on which social and cultural conflicts are fought. A key issue has been the creation of cultural authority through communication. As a result, current research in linguistic anthropology has considerable significance in the study of political and economic formations, scientific and religious enterprises, as well as in the more traditional study of group boundaries and social identities. Contemporary linguistic anthropology provides the semiotic concepts necessary to understand how social institutions – including "language" and linguistic structure – are reproduced, authorized, and continually transformed.

Linguistic anthropology is the study of language **in** culture and society. The field analyzes linguistic practices as culturally significant **actions** that constitute social life. The situated use of language is exemplary of the meaning-making process that shapes a social worlds saturated with contrasting values and contested interests, with opposed political positions and identities, with variable access to institutions, resources and power. Linguistic anthropology examines the role of social interaction – and the semiotic processes on which it relies – in making, mediating and authorizing those contrasts and differences. Aspects of context enter into this process through linguistic form itself, as form signals speaker alignments and cultural presuppositions that are called into play during social interaction. Presuppositions invoked during interaction can draw on any cultural realm: categories of contrasting identities, folk ontologies, notions of truth, space, time, cosmological order, and morality. Such presuppositions are invariably linked to language ideologies, that is, culturally specific conceptions about language and its role in social life.

Recent research on language-in-context has resulted in new definitions of the field's fundamental concepts: 'language' 'metalanguage' 'discourse' 'context' 'event' and 'text.' Metalanguage is crucial because it makes possible the reflexivity that is a necessary feature of verbal interaction. Reflexivity has methodological as well as theoretical implications. Speakers' categories of speech, events and personae are reflexive in that they create frames of interpretation for social interaction and are not necessarily uniform within any group. They are indispensable starting points for empirical investigation of talk. Such categories provide perspectival views on interaction and contrast with the linguists' own perspectives and direct observations. Scholarly discourses and debates about language are of theoretical interest as well. Like the metadiscursive categories about language and interaction of ordinary speakers, expert debates also create frames of interpretation; they participate in cultural systems, and often legitimate relations of power.

In concert with some poststructuralist philosophies, yet in quite different ways, linguistic anthropology analyzes linguistic practices not only as the instruments of social life, but rather as the **ground** on which social and cultural conflicts are fought. A key issue has been the creation of cultural authority through communication. As a result, current research in linguistic anthropology has considerable significance in the study of political and economic formations, scientific and religious enterprises, as well as in the more traditional study of group boundaries and social identities. Contemporary linguistic anthropology provides the semiotic concepts necessary to understand how social institutions – including "language" and linguistic structure – are reproduced, authorized, and continually transformed.

Terms and Turfs

The label 'linguistic anthropology' was coined in the late 19th century by scholars at the American Bureau of Indian Affairs who collected folkloric material among native Americans. Its current use in the United

States dates from the early 1960s, when 'linguistic anthropology' became a cover term for the study of language in social life and conversely for the study of social context in shaping linguistic structure and use. Two commitments have remained central to the field, and link it distinctively to anthropology: First, ethnography is its indispensable methodology, though augmented by elicitation, interview and audiovisual technologies. Second, linguistic form and function are studied within a cross-cultural, comparative framework, with attention to human universals along with historical, regional, and power-laden sociocultural differences.

A set of other hybrid labels emerged at roughly the same time, also proposing to study language in social, cultural and psychological terms. Scholars from a number of disciplines came together under labels such as: sociolinguistics (later split into interactional and variationist), ethnography of communication, linguistic stylistics, linguistic pragmatics, psycholinguistics, ethnomethodology, ethnolinguistics, conversation analysis, discourse analysis, interactional analysis, sociology of language, and anthropology of language, among others. Some of these terms became alternate designations within linguistic anthropology (e.g. ethnography of communication, interactional sociolinguistics), others have come to mark differences of emphasis (e.g. discourse analysis, pragmatics). Still others, like variationist sociolinguistics and conversation analysis, have developed characteristic methodologies, remaining closely aligned with their disciplines of origin – linguistics and sociology respectively.

The intellectual excitement and energy evidenced by the proliferation of terms, conferences, and edited volumes in the 1960s was an ironic response to the establishment of separate departments of linguistics in American universities in the post-WWII period. These departments provided institutional backing for the formalist study of language as an autonomous phenomenon, putting aside concerns with the contexts of language. They thereby indirectly re-invigorated such contextual questions in other institutional venues. Only psycholinguistics was directly spurred by generative grammar, which legitimated cognitive questions in the face of the reigning behaviorism. The new contextual fields were surely also encouraged by more funding for cybernetics and 'communication research,' which became policy sciences during the Cold War.

Within anthropology, the new labels joined the much older term 'anthropological linguistics,' which was closely tied to fieldwork-based typological research on native North America languages as established by Franz Boas in the early 20th century. Those who now adopt the label of anthropological linguistics are oriented to linguistics departments, to descriptive work in the structuralist tradition or to historical reconstruction of language and verbal art in unwritten languages. Those identifying as linguistic anthropologists orient to anthropology departments and to language and speech as cultural practice. Many individual scholars are active in both kinds of research. Differences of emphasis notwithstanding, linguistic anthropology and anthropological linguistics have been used interchangeably as labels in textbooks and encyclopedias. The Boasian tradition gives linguistic anthropology significant institutional recognition, intellectual influence and prestige within the discipline of anthropology.

In the hybrid fields of the 1960s, practitioners held themselves accountable to different departmental audiences (linguistics, sociology, anthropology), resulting in different emphases and preferred topics. Collections of articles in the last few decades, however, have usually included scholars from several disciplines, all writing on a single theme. The roster of substantive topics has included: the linguistic marking of social relations and identities; conversational interaction and other speech genres; political processes mediated by speech such as decision-making and dispute settlement; language and nation; multilingualism, linguistic variation and multidialectalism; standardization and literacy; national language policy; narrative, performance, verbal art and ritual; the emergence, circulation and desuetude of languages, linguistic varieties, registers and styles; the acquisition of cultural competence through language; the relation of cognition to linguistic categories as coded in grammars and lexicons; the mechanisms of language change. The last half century has also brought new issues such as the globalization of languages and the effect of novel communicative technologies.

Roots and Shoots

Linguistic anthropology is often called an interdisciplinary field. But considered as an intellectual (rather than a departmental or institutional) endeavor it is rather a set of lineages or kinship lines that are read and invoked for inspiration and legitimation. As in all segmentary lineage organization, naming one's ancestors is also a means of forming alliances and oppositions in today's controversies. (What the field would analyze as the relation of narrated and narrative event.) This very brief recitation of family ties is not a history of linguistic anthropology but an overview of a usable past on which current practitioners rely.

The turn of the 20th century is the conventional starting point, especially the work of Franz Boas,

Edward Sapir and their students. They collected textual materials to document peoples whose cultures were rapidly changing under brutal colonial pressure. These scholars were inspired by the previous century's German tradition that considered language as a historical guide to the customs and values of a group. Starting with Boas's studies of verbal art and folklore, poetics has played a continuing role, strengthened by contacts with parallel interests among Prague School linguists. Contact with avatars of European dialectology of the 19th and 20th centuries helped raise concerns about regional distributions of forms, definitions of languages, standardization, dialect boundaries and historical change. A francophone line of structuralist linguistics starting with Saussure, through Benveniste, is perhaps best characterized as the immediate source for the autonomous linguistics that has been linguistic anthropology's intellectual foil. In this respect, at least, American structuralists from Bloomfield to Harris to Chomsky have been the heirs of Saussure. For linguistic anthropology, by contrast, Saussure's project is significant as part of a broader understanding of sign phenomena.

The other sources of sign theory were the Americans C. S. Peirce and to a lesser extent the more behaviorist Charles Morris. The significance of Peirce's semiotics for linguistics was emphasized by Roman Jakobson, himself a central node in a kin network that connected American structuralism to Prague School functionalism and Russian formalism while also helping to bring the work of Bakhtin's decidedly anti-formalist Russian school of poetics and literary studies of the 1920s and 30s to international attention. Literary studies have repeatedly been 'captured' as relatives by linguistic anthropology, or vice versa, as in the mid-century dramatism of Kenneth Burke, the semiotic readings of Roland Barthes, or the writings of Raymond Williams and other neo-marxist critics. There were also the quasi-literary interests of Malinowski in language function and 'context of situation,' not taken up by British social anthropologists but rather by functional linguists and later in the century within anthropology by Gregory Bateson.

Philosophies of language have also been significant interlocutors for linguistic anthropology. Austin's ordinary language philosophy was particularly important as it side-stepped the Fregean concern with truth conditionality. This was followed by Searle and Grice on speech acts and implicatures, and in a different line by Wittgenstein on language games. A later and contrary branch of this lineage is represented by Hilary Putnam and Saul Kripke on the indexicality of reference. Finally, linguistic anthropology rightly claims important kin connections with phenomenologists such as Husserl who inspired sociologists from Schutz, to Goffman to Garfinkel, though these doubtless also saw themselves as descendants of G. H. Mead, himself very likely a reader of Peirce.

Relying on all these sources, linguistic anthropology was consolidated in the 1960s through two intellectual strategies familiar from the history of science: The first was a bid to constitute an 'object' of analysis that had not before been the focus of research. Most broadly stated, this object was the process of face-to-face interaction. One can rephrase the argument this way: the primary datum for all the ethnographic and language-based disciplines is the contingent stream of eventful talk in everyday life, along with its concomitant non-verbal signaling systems. Each disciplinary enterprise abstracts from this in a principled manner. What is not within its focus becomes an obstacle to research and is bracketed or theoretically discounted. For instance, Saussure was quite explicit that a synchronic linguistics should (for the moment) ignore what he defined as 'external' though admittedly important facts, instead studying structural relationships of contrast and opposition he defined as 'internal' to language. In a parallel way, the sociocultural anthropology of the 1960s treated language as a vehicle for recounting cultural content, thereby excluding from study the situation in which the telling occurred.

This first project has had considerably success. Linguistic anthropology abstracted something new from that accessible stream of verbal activity, finding systematicity where others had found only noise: Goffman's "neglected situation;" "naturally occurring talk" and 'conversation' as defined by Schegloff and Sacks; the "speech event" and its functions, as defined by Jakobson; studies of performance genres by Hymes, Friedrich, Albert, and Ervin-Tripp; Barth's notion of interactions as boundaries; Austin and Searle's "speech acts," and the organization of "social meaning" that Gumperz and Labov found in linguistic variation and codeswitching. Goffman declared the relative analytical independence of an "interactional order" governed by a separate set of principles not directly related to larger social structures. There ensued a period of description, typologizing, and cross cultural comparison.

The second, more radical intellectual project was a double-edged critique, targeting both linguistics and social science as then constituted. Hymes's dictum was a classic performative, disguised as mere description: "... whereas the first half of the century was distinguished by a drive for the autonomy of language as an object of study and a focus upon description of structure, the second half was distinguished by a concern for the integration of language in sociocultural context ...." (1964: 11). This project continues

to inspire theory and research. It has produced detailed criticisms of mainstream linguistics, sociology and anthropology.

In the argument with generative linguistics, linguistic anthropology retained much of structuralist analysis, but rejected the asocial definition of language. What had been peripheralized became central in a series of changes in focus. Linguistic anthropology emphasized multilingual, stratified speech communities instead of the ideal hearer/speaker; performance instead of linguistic competence; linguistic repertoire and speech act instead of abstract grammar and sentence; speech acts and speech events instead of the disembodied sentence. As sources of evidence, contextually located and tape-recorded interaction replaced intuitions about grammaticality. Some of this dovetailed with European initiatives to study sentence level phenomena through their cohesion into larger units. In mainstream American linguistics, however, the subjects taken up by linguistic anthropology were relegated to subfields such as pragmatics and sociolinguistics.

In sociology, it was methods and epistemology that were attacked by language-centered approaches. Study of interaction highlighted the situatedness of all sociological descriptions, indeed the unavoidable role of the interviewer in shaping the answers that made up a sociological report. This insight about the 'reactivity' of measurement was recognized as important, but was so corrosive to sociological business-as-usual that it was isolated as the workings of a 'micro-order,' to be studied separately from the institutional, organizational and demographic issues that occupied the mainstream of sociology. Without theories of how micro and macro were linked, there was a continuing side-lining of language as subject matter, and the trivialization of interactional process as merely the enactment of patterns determined elsewhere, the faithful reflection of supposedly more powerful 'macro' forces.

The role of linguistic anthropology within anthropology was more complicated. The position of language was significantly transformed in the 1980s in two ways. First, through a redefinition of culture. Rather than a symbolic or cognitive phenomenon (the two previous approaches) culture came to be seen as a set of embodied practices within institutions; practices that, in certain conjunctures, could change the institutions themselves. 'Language' was often invoked as a powerful means of constructing reality. Ethnographies of speaking that analyzed race, gender, ethnic conflict or dispute settlement fit well into practice theories such as those inspired by Bourdieu, by Birmingham cultural studies, colonial studies and Gramscian notions. But even when recognized as important, linguistic practice was rarely analyzed in any detail.

Simultaneously, a second enterprise was also launched, related to language but largely independent of linguistic anthropology. Under the influence of literary studies, anthropology mounted a reflexive critique of the poetics and rhetoric of anthropology's own prose genres, especially ethnographic monographs. Anthropologists joined continental theorists such as Foucault and Derrida in unpacking and undermining the idea of objective knowledge. Metadiscourse, texts, their materiality, their authorization, their ability to 'objectify' and devalue others, all took center stage in sociocultural anthropology. But these concerns were often separated from the classic ethnographic and comparative goals of the discipline. For linguistic anthropology, the poststructuralist philosophers' discussions of discourse, rhetoric and poetics as shapers of 'truth' and subjectivity rang familiar tunes – if in unfamiliar keys. As a result, they provoked spirited responses. This critical engagement was guided by the internal logic of linguistic anthropology itself during intensive discussions in the 1980s and 1990s. The debates with poststructuralism encouraged a synthesis within linguistic anthropology that was aimed at developing a processual, event-based, political economy of texts in social life, and a semiotic perspective on culture.

The overall project of linguistic anthropology remains the reshaping of linguistic theory from an interactionalist and culturalist perspective, and the revamping of anthropological investigations of meaning and action from the perspective of a semiotically grounded understanding of language, culture and social institutions. Within these broad aims, the last twenty years have brought substantial revisions in theoretical concepts.

Concepts and Controversies

The orienting concepts discussed here are not strictly separable; there are overlaps and echoes among them. Each section traces continuities with earlier formulations, discusses points of recent controversy and consensus, and then outlines briefly the implications of current approaches in linguistic anthropology for both linguistic and anthropological theory.

Indexicality, Metalanguage, Materiality

The multifunctionality of language was a pillar of 1960s linguistic anthropology. Jakobson (1960) enumerated emotive, poetic, metalinguistic, phatic and conative (action) functions. These operate simultaneously. Depending on the nature and goal of interaction, some are highlighted more than others. Yet

linguistic anthropologists observed that in many cultural contexts experts and laypeople alike privileged referentiality, believing that the naming of things in the world and predication about them was the pre-eminent role of language. Early linguistic anthropology proposed the category of 'social meaning' to designate what is communicated through a disparate set of formal linguistic devices in which picking out a referent is only secondarily involved, or absent altogether. These included Labovian phonological markers of class or regional identity, speech levels, grammatical alternates specific to males vs. females, avoidance registers, and codeswitching between languages and dialects.

The conceptual unity of these phenomena has been clarified through more concentrated attention to the non-referential, metalinguistic and poetic functions of language. This has been done through a foundational critique of structural linguistics, fortified by a culturalist reading of Peircean semiotics.

The structuralist tradition of grammatical analysis, no less than western common-sense, implicitly relies on the assumption of a stable referentiality for linguistic units. Saussure created a semiotics in which signs link a concept (signified) with a sound image (signifier) in systems of value-creating contrast. But he left unanalyzed the circumstances under which signs would be instantiated. His form of structuralism is able to explicate the workings of grammar as a system of oppositions, sequences and substitutions. But severing an abstract system of types (*langue*) from their tokens in contexts-of-use (*parole*) had serious limitations. Most importantly, it could not analyze what Jakobson called 'shifters:' linguistic phenomena whose referential value is not entirely fixed within an abstract system, but relies in part on features of the situation in which they are used. There is no type-level stability in the reference of 'I,' it varies with the instance of utterance, always identifying the speaker of the moment. More generally, not only reference but also the interpretations of speech acts, implicatures and presuppositions are necessarily linked to events of speech.

Thus, speech as social action is not adequately described as the 'putting to use' of a separately analyzed grammar. On the contrary, grammar is full of devices – deictics, tense, mood, evidentials – that gain their interpretation only in part from type-level contrasts, and in part as tokens of use in specific contexts. These phenomena make an autonomous grammar impossible in principle: to describe them fully one needs pragmatics. That is, the speech event in which they occur must be analyzed in ethnographic detail and systematically linked to linguistic form.

To do so, Jakobson drew on C. S. Peirce's triadic semiotic theory in which a sign is linked to an object for an interpretant. Indexical signs, for Peirce, stand for their objects by virtue of a culturally noticed, real-world contiguity. In contrast to symbols, defined by Peirce as signs that stand for their objects by virtue of a general law, indexes simply point to their objects; they signal through a co-existence between the sign and the objects and speech events of its occurrence. In these terms, shifters are partially indexical, partially symbolic. As Silverstein (1976) argued, the linguistic phenomena earlier identified as having "social meaning" (e.g. phonological variants, codeswitches) are non-referential indexes, relying for their interpretation on their continguity (indexicality) with contextual features of the speech event in which they occur. That is how a phonological variant can signal the social relations of the speakers in an event, their relation to the topic of talk and/or the nature of the event itself. Non-referential indexes can be placed on a continuum with shifters. Indeed, the philosophical work of Putnam and Kripke showed that any act of reference necessarily has an indexical component. Referential indexes (shifters) and non-referential indexes have two further significant properties. They need some metadiscursive frame in which to be interpreted (see next section). And they can be either presupposing or creative. If presupposing, then their use signals that some aspect of the context is taken for granted as existent; if creative/entailing, then the use of the form itself brings into social relevance (into apparent 'existence') the objects or categories with which the form is culturally associated.

By linking shifters and non-referential indexes, a Peircean analysis provides a conceptual unity to social indexicals and thus to what used to be called 'social meaning,' thereby clinching the case against an autonomous grammar. It also provides conceptual materials for an alternative theory of linguistic structure. Classic empirical studies of indexicals include Errington's work on speech levels in Java; Silverstein's re-analyses of Labovian phonologoical variables and of T/V pronoun usage in the history of English; Irvine on Wolof registers; Ochs on indexicals of gender and stance in language socialization; Duranti and Agha on honorifics; and Haviland on Australian avoidance register. Brown and Levinson handled politeness phenomena, which are also of this kind, with a decidedly different approach.

The presumption that referentiality and propositionality are the pre-eminent functions of language is part of an ancient western ideology. Not as old, but still powerful is the related idea that metalanguage and poetic forms are mere ornaments to reference. Because language has so often served as a model of culture, these widespread assumptions have implications for anthropological theory. For instance,

Levi-Strauss borrowed from structural linguistics the idea of distinctive features; ethnoscience borrowed generative grammar's idea that there are rules of competence. Interpretive anthropology borrowed from philology the notion of text. In each of these otherwise different cases, it was the referential capacity of language that served as the model for culture. Culture, like grammar, was seen as organized symbolic content that could be extracted from the real-time social action and historical positioning in which it was created. This taken-for-granted move of decontextualization reproduced the Cartesian assumption of a chasm between world and word. Accordingly, approaches in anthropology that emphasized practice, political economy and materiality were assumed to be opposed to those concerned with meaning, representation and ideation.

In contrast, a linguistic anthropology that places indexicality and speech-as-action at the center of attention provides a different synergy with sociocultural anthropology. Propositionality, however significant, is recognized as a feature peculiar to language. It is least like the rest of culture. Instead, the indexical aspects of linguistic practices, as interpreted by metadiscourses, are among the best examples of cultural meaning-making. Indexical signs are not only linguistic; they are also gestural, visual and sartorial, among other modalities. They are not 'reflections' of some other, more (or less) important reality. Rather, they are constitutive of the real-time creation of social-material reality through interaction. Peircean semiotics, with its tripartite emphasis on the **object**, as mediated by the sign and interpretant, insists on the materiality of communication, and conversely on the semiotic organization of material practices.

Context and Contextualization

Speech events were a fundamental unit of early linguistic anthropology. Studies focused on their constituent features (e.g. speaker, hearer, topic), social functions and cross-cultural typologies (e.g. Gumperz and Hymes, 1972; Bauman and Sherzer, 1974). In the last few decades, the structural description of speech events has been transformed into a more flexible concern with the 'context' of discourse and performance, bringing several important changes in the understanding of context. Good overviews of these issues are offered by Bauman and Briggs (1990), and Duranti and Goodwin (1992). The notion of 'context' as a set of social, spatial and physical features surrounding talk was commonsensical but inadequate. It implied the possibility of infinite regress in the number of features; it neglected the perspective from which context was viewed; and it assumed a firm divide between talk and context. The problem of infinite regress arose from the effort of the analyst to list exhaustively the factors that might affect the nature and form of the talk. In order to choose which of the many features are relevant, one must address the question of perspective. Features defined from the point of view of the analyst are useless for understanding social process; it is the selective attention by participants to aspects of the social surround that analysts ought to be describing.

Conversation analysts such as Schegloff, Sacks, Jefferson, Heritage, Charles and Marjorie Goodwin took as an axiom the importance of discerning what participants orient to on a moment-by-moment basis in the local management of sequential talk. Participants need not share perspective among themselves any more than they do with the analyst. They might well have to negotiate a definition of the situation. Context then becomes a joint accomplishment. Infinite regress is avoided because it is the participants who together signal when 'enough is enough,' or defeat each others' attempts to include more (or less) of the surround. Such signaling is not necessarily propositional speech, yet is certainly communicative. Talk itself signals the frames for its own interpretation, supplying the cues for what is to be taken as its own context. There is no firm divide between a strip of talk, its co-text (linguistic context) and its sociocultural context.

It is not context, then, that is of interest, but contextualization: how participants attend to on-going discourse, conveying their assessments, evaluations, presuppositions as well as predictions about the definition of the activity that is occurring, the event-specific roles of the participants, the intentions of speakers, the direction the activity is likely to take, as well as unexpected switches in all of these. This process relies on culture-specific folk theories about social actors, intentions, events and goals, while recreating those very categories in the process of communication. These theories are not necessarily shared. What Putnam observed about the lexicon is equally apt here: in any group there is likely to be a division of linguistic labor and of the expertise it requires. In addition to local knowledge, contextualization relies on the universal metacommunicative capacity of language, and on the universal ability of speakers to attend to and respond to metamessages about the relationship of talk to its surround.

The several concepts that have been crafted for the analysis of this metacommunicative process differ in certain respects, but bear a family resemblance. Lucy (1993) provides a good review of these. Bateson proposed 'framing' to denote metamessaging that signals some activity to be play or not-play. This is

common even among many non-human animal species. Chafe and Fillmore made linguistic use of this formulation. Goffman (1979) extended it with his notion of the footing or stance taken in an interaction, and the participant roles or role fragments – such as 'author' 'animator' 'principal' of an utterance – that are thereby evoked. Philips described participant structures, and Cicourel proposed the notion of schema for related phenomena. Gumperz (1982) introduced contextualization cue to name the many kinds of linguistic signals (e.g. prosody, codeswitching) from which one infers what kind of activity is in effect. Silverstein (1993) distinguished between metasemantics, by which speakers define the meanings of words, and metapragmatics. Metapragmatic discourse is explicit commentary or evaluation of language use (e.g. that some event was gossip). Metapragmatic function, by contrast, is implicit signaling to suggest which cultural frame or activity is in effect. Bakhtin (1981) and Voloshinov proposed literary analysis of reported speech and voicing as metacommunicative devices that present the perspective of one speaker on the speech of another. Bauman (1986) showed that performance is itself reflexive: the speaker assumes responsibility for speaking well, thereby drawing attention to the code and poetic forms through which speech genres are created and thus expectations about them are signaled.

A crucial aspect of framing or voicing is the possibility that frames can be embedded in other frames; they can be transposed and projected both forward and backward in time. Furthermore, speakers create interactional tropes, treating interlocutors and events 'as though they were someone/something else,' thereby achieving novel communicative and social effects. As part of such effects, voices can be reported in quotation or in various forms of indirect discourse. Social interaction is thus an endless lamination of narrated events and the narrative events within which the stories are told. For linguistics this implies a complexity in patterns of pronouns, tense, evidentials, discourse markers and anaphora that signal such embeddings of frames. These cannot be handled without theorizing indexical phenomena. For sociocultural anthropology the embedding of frames and their interpenetration during narratives and conversation allows analysts to understand processes such as the relationality of personhood and the fragmentation of selves, as well as subject formation, role-distance, and the cultural conceptualization of what counts as authenticity. It is a small example of the reality-constructing processes involved in reported speech that the speech reported need never have happened, or not in the way reported. Yet the report – culturally framed as, say, gossip, journalism, court testimony, or oracle – can have far-reaching consequences in shaping subsequent social relations.

Framing and the propositional content of talk always occur simultaneously. Metamessages allow the analyst to track participants' interactional moves in an encounter. These moves (the interactional text) include the open-ended set of acts that can be done with words: promises, teases, threats, and the unnamed, more general alignment or antagonism among speakers. These acts are accomplished in part by small observable behaviors such as sequencing, body position, and conversational repair. But they are just as importantly accomplished by the ways in which the names for objects and actions that are the subject matter of talk are selected from the many equally accurate denotational labels available. As Schegloff (1971) pointed out for the limited case of place-names, how one formulates a label is always relative to a particular event of talk, that is, indexical. Selection of a term that picks out a referent involves a delicate (and not always conscious or aware) negotiation of social relationships, assumptions about participants' levels and types of knowledge, hence their identities and social location. In turn, the use of one rather than another referring expression is creative/performative. The difference between 'dine' 'take a repast' 'chow down' or 'put on the old nosebag' is not only a matter of lexical register. Each claims a speaker identity, positions speakers with respect to each other, with respect to the event, the referent, and to the cultural discourses indexed by the labels selected. Framing and the indexicality of reference together accomplish contextualization: the moment-by-moment means through which interaction creates and transforms social relations.

Text and Entextualization

There is an irony in the effort of linguistic anthropology to discern how participants contextualize stretches of discourse. For scholars themselves spend most of their time ripping snippets of discourse out of context in order to translate, transcribe and analyze them. The process of decontextualization is a key (reflexive) step in social science methodology. Yet the examples of transposition, reporting the speech of others, and embedded frames discussed earlier show that decontextualization is just as familiar from everyday life. It is the flip side of contextualization. This is what Bakhtin evocatively characterized as our mouths being full of other people's words. It has been a focus of analysis in linguistic anthropology for the last two decades.

Close analysis of the process requires a distinction between 'text' and 'discourse.' 'Text' is any

objectified unit of discourse that is lifted from its interactional setting. 'Entextualization' is the process of transforming a stretch of discourse into such a unit of text, undoing its indexical grounding by detaching it from its co-text and surroundings, yet taking some trace of its earlier context with it to another setting which is thereby changed and which reciprocally transforms the text itself. Certain formal properties can enhance the likelihood of entextualization. For instance, poetic features of cohesion, or genre conventions can signal a boundary to an interaction, therefore a chunking of text. But any stretch of discourse can enter into interdiscursive relations by which it seems to be recalled, repeated or echoed in further discourse. It can be picked out and seemingly frozen as text, to be involved in further intertextual relations that link it to previous and subsequent versions of text. Interdiscursive and intertextual links create the impression that text fragments 'circulate' across texts, events and among speakers.

The linguistic means of entextualization are the same metadiscursive signals that are essential for contextualization: devices of framing, cueing, metapragmatic discourses and functions. For the purposes of linguistic analysis, it is necessary to study the transformations that discourse undergoes as it is entextualized and then (re)contextualized. Footing or genre might change, as might indexical grounding (as signaled by changes in deictics of person, space and time). The function of the text might also change (e.g. from everyday act to ritualized tradition). New forms, functions and meanings may be emergent in the newly re-contextualized text. And there are questions of access, power and inequality involved in the social arrangements that constrain what sorts of persons and statuses can entextualize in what institutional settings. Processes widely analyzed under other names – translation, codeswitching, glossing, among others – are amenable to further scrutiny in these terms. Furthermore, by cultural definition, some texts are more or less accessible for de- and recontextualization.

The anthropological implications of this line of work extend in at least three directions. First, such analysis can reveal how the social magic of authority – political, legal, epistemic – is created in and across interactions. The relationship between narrated event and the story-telling event in which it occurs is a delicate nexus at which to 'calibrate' voicing through the projected relations of teller to tale, to audience, to source, and to previous and subsequent events and tellings (Silverstein, 1993). Through metapragmatic framing, speakers can construe the interactive event that is recounted as being distinct from the on-going event of talk (reportative calibration), or as the same event (reflexive calibration), or as emanating from some other epistemic realm such as the sacred, the universal, or mythic (nomic calibration). Within specific institutional settings, these calibrations create different sorts of authority: claims to knowledge, or claims to (and the social effect of) speaking as/for the people, the ancestors, the gods, or the laws of science. Contests over the metapragmatic framing of sources for statements can create (and destroy) the authority of texts and hence the power of speakers. As Silverstein and Urban (1996) note, a significant part of politics is the struggle to entextualize authoritatively. Linguistic practices, then, are the very grounds of politics, not the medium, description or reflection of them. This includes the assignment of responsibility and blame, credibility and doubt. Hill and Irvine (1993) show that across widely different cultural settings, such attributions are managed through metapragmatic devices such as reported speech and the distribution of voices across participant roles.

Second, the processes of entextualization and links among texts (intertextuality) allow a deeper understanding of temporality, spatiality and social connectedness. Despite the undeniably linear, sequential ordering of speech, there is no single 'now' in interaction. Any utterance is weighted with the earlier source from which it can be heard to have originated, and the implicit future recounting in which it might participate. The interdiscursive links among interactional contexts can be extended and projected without temporal limit (Irvine, 1996). Even within a single narration there are often layered successions of retellings which, embedded in each other, can make traditionalization visible as a temporal process. Similarly, study of intertextuality can highlight systematic relations among events in spatial extension, inviting scholars to rethink the relation of face-to-face interaction and what used to be called 'larger social structures.' This will require further theorization of the various kinds of linkages between interactions. For instance, we need to know how circulation – a shorthand term for intertextual links, echoes, repetitions – has differential 'reach' across interactions that are distinguished according to their degrees and types of instutionalization, geographical range, political economic consequentiality, form of mediation as broadcast, print, or face-to-face talk. The phenomenon of translation (linguistic, cultural) deserves considerably more attention in these terms, as it too is a form of multiply layered intertextuality.

Finally, there are methodological implications of this perspective on text. Social science research always involves reflexive language. Jakobson remarked that there could be no linguistics without metalanguage,

as scholars have to ask for glosses, acceptability judgments and paraphrases. The reactivity of fieldwork became an issue for sociocultural anthropologists of the 1980s, (just as it had for sociologists in the 1960s) when they noted that fieldwork is 'dialogic.' It is not the positivistic observation of an object by a subject but an encounter between two subjects – the informant and the anthropologist – with different relevances, values, and different sets of ultimate audiences in mind. Much of the subsequent critical commentary focused on issues of objectification in ethnographic writing. Less attention was paid to the fieldwork encounter itself as dialogic and mutually objectifying. Like any interaction, fieldwork and interview are always susceptible to the confusion of mismatched or even incommensurable metapragmatic signals among interactants that Gumperz called 'cross-talk,' and that is made worse by power differentials. This is less a problem specific to anthropological research than an insight about the nature of human interaction. As Mannheim and Tedlock (1995) have remarked, the people anthropologists study have been 'objectifying' each other well before the arrival of the fieldworker. The task is to specify what kinds of objectification and incommensurability in metacommunication are operating, and how.

Language Ideologies

Language ideologies are cultural conceptions about language, its nature, structure and use, and about the place of communicative behavior in social life. Useful definitions and exemplary studies are presented in Woolard and Schieffelin (1994) and Schieffelin *et al.* (1998). Ideas about speech and language are common in all social groups and are as culturally diverse as linguistic practices themselves. In the linguistic anthropology of the 1960s the study of language attitudes and native models of politeness, language variation, honorifics and appropriateness were grist for cross-cultural typologies and comparisons. These research themes, along with others detailed below, are unified under the rubric of language ideology.

The term 'ideology,' though polysemous, most often evokes ideas connected to politics and power. Such concerns have a long pedigree in linguistic anthropology. Boas as public intellectual brought anthropological and linguistic evidence to bear against racist science and anti-immigration policies. Overtly political concerns about inequality and race were also present in the 1960s, for instance in the debates among Bernstein, Hymes, Gumperz, Kay and Labov on the existence, value, and consequences of 'restricted codes' in working class and Black speech. Current controversies that have strong political implications include the increasingly global hegemony of English, the linguistic mediation of inequality, the future of endangered languages, and the stigmatization of multilingualism and of certain accents and dialects. What is different today is scholars' reflexive analysis of communicative processes in their own work and in large scale politics.

Language ideologies always include metapragmatics, that is, local suppositions about the relation of speech forms to speakers' identities and their social situations. But language ideologies are never only about language. They include whatever other conceptual systems are taken to be relevant to language by the speakers and institutions under study. In the analysis of language ideology, as in the study of metapragmatics, there is a split between those approaches privileging explicit, propositional content, and others that focus on implicit ideological patterns inscribed in linguistic, institutional, ritual and other material practices. Language ideologies are never unitary and so the study of ideology commits the theorist to a perspectival approach. As Woolard has emphasized, one must ask: whose ideology is at issue and in what practices and institutions is it sited. There are likely to be contradictions among ideologies. For instance, Bateson's notion of the double bind consists of two contradictory ideological (meta) messages, delivered in different modalities simultaneously. There is also likely to be contestation among ideologies evident at different social locations. Nor are ideologies likely to be shared within social groups in a world characterized by linguistic divisions of labor. In a single population, language ideologies inscribed in the practices of schooling can conflict with or override those evident in families, friendship networks or other institutions, raising questions about the relative authority of different ideologies.

Early discussions of 'linguistic ideology' emphasized the tendency of explicit ideological statements to rationalize and thereby distort linguistic practices. Boas and Bloomfield saw speakers' models of their own speech as obstacles to genuine linguistic analysis. More recently, scholars have noted that there is no access to linguistic materials except through the filter of metalinguistic assumptions – whether these are the assumptions of speakers and/or of analysts. Current use of the term 'language ideology' considers such filters not as regrettable distortions but as part of the perspectival nature of ideologies, their necessary partialness and partiality. This includes the perspective of linguists. Language ideologies are grounded in social position and experience, in moral and political stances. But they are not an automatic reflex of these. Rather, ideology mediates between social position and linguistic practice in diverse domains. Students of language

socialization (Ochs and Schieffelin, 1994) have shown that children do not simply learn linguistic skills. Rather, local ideologies mediate between talk itself and assumptions about the proper relationship between childhood, talk and forms of mothering. Similarly, in the study of literacy, Collins finds that language ideologies add their own contributions as interpretive filters, defining who can be expected to read and write in what way and for what purpose, thereby contributing to the creation of many distinct forms of literacy. The linkage between linguistic practices and categories of identity is also mediated by language ideologies. How are maleness and femaleness indexed in speech? When such indexes appear in interaction, other dimensions of social life – such as the expression of desire, sexual activity, typified emotions, rank and social position – are entailed, in part on the basis of local cultural images of masculinity and femininity (Cameron and Kulick, 2003).

By viewing language ideology as an inescapably perspectival lens on social interaction, linguistic anthropology engages in debate with neo-Marxist lineages of ideology-critique. Some studies in linguistic anthropology have marshaled evidence from language use to challenge social theorists' proposals about the workings of symbolic domination and cultural hegemony. Other work has reconsidered influential formulations about ideology by Bourdieu, Foucault, Althusser, Žižek and others to reveal their unexamined assumptions about language and semiosis. Social theorists of ideology often and unreflectively rely on implicit linguistic models that, because they seem commonsensical or self-evident, help to make their theories more persuasive. Most generally, ideologies that present themselves as concerning language can work as displacements or coded stories about political, religious or scientific systems; ideologies that seem to be about religion, political theory, human subjectivity or science are often implicit entailments of language ideologies, or the precipitates of widespread linguistic practices. The term 'displacement' can be further analyzed here as a form of voicing. However, to recast a language debate as a coded dispute about religion, aesthetics, morality or politics is not, in itself, an explanation. Rather, the goal of analysis in studies of language ideology is to show **how** such a displacement works in semiotic terms, how it is instantiated in practices, and how it legitimates, justifies or mediates action in quite other areas of social life. Conversely, a particular definition of language may itself be made more credible by its connection to other, non-linguistic, sociopolitical concerns and especially to their supporting institutions.

Ethnolinguistic nationalism provides a familiar example. Over several centuries, European philosophical and political practice did the ideological work of making the connection between the cultural categories of 'language' and 'nation' appear a necessary, natural and self-evident one, united as much in everyday political practice as in scholarly arguments. This occurred in part through the establishment of a science of language that defined a bounded and unified object of study ('language') as a natural entity, out there to be discovered. The ideologically constructed unity of language-and-culture in a populace was seen as the ultimate source of political authority: those who spoke one language constituted a 'people' whose united voice would replace the authority of imperial rule. By this logic, any group claiming to speak the same language could use that fact as proof of its nationhood and thus justification for a state of its own. A somewhat different example of authority through language ideology is the political theory of the 'public sphere' as guarantor of democratic politics. According to European notions of a public sphere, as dissected by Habermas, the worth of a speaker's argument is judged not by speakers' social status. Ideally, democratic citizens make anonymous contributions to policy debate and to critiques of the state. It is the form and rationality of their contributions, not their identities, that is supposed to guarantee the fairness of a democratic polity. From the perspective of this theory of democracy, it is evident that a model of ideal linguistic interaction underpins the semblance of impartiality and hence the legitimacy of democratic process (Gal and Woolard, 2001).

It is not only politics that is legitimated by images of language and social life. Bauman's study of Quakers and Keane's more recent report on Christian missionizing both suggest that the relations envisioned between speakers and listeners within these religious communities implied forms of interiority and intentionality that became models for various forms of Christian belief. Other forms of belief are also underwritten by understandings about language in social life. For instance, Shapin's historical account of 17th century science shows that polite conversation among gentlemen was the model that, when transferred to gentlemanly interaction at the Royal Society, created the credibility and assumed replicability of early scientific experimentation. In these examples, linguistic ideologies underpin social institutions, providing the supposedly self-evident background that authorizes new social forms.

Language ideologies are cultural frames. As such they have their own histories, which are instantiated and circulated in specific institutions and genres of speech and writing such as the etiquette book, instruction in oratory or realist novel. Another such genre in the west is linguistic philosophy. Its analyses

are supposedly universal, yet very much rooted in the history of European cultural understandings about language. While the notion of 'intentionality' of the speaker is a key term in western philosophy of language, comparative study shows this to be but one historically specific version of an interiority-centered language ideology. As Duranti and Rosaldo have shown, in many social groups outside of Europe, inferences about speakers' intentionality are not decisive or indispensable in the interpretation of speech acts. Bauman and Briggs's study of the western philosophical tradition focuses mainly on Herder and Locke, tracing the historical conditions out of which emerged the regimentation of linguistic practices that would subsequently count as examples of 'folklore' on the one hand, and 'objective speech' on the other. Another such genre is linguistics analysis itself, especially as it has intersected with colonial projects. Historical studies show how language ideologies fit into fields of debate with which they are contemporaneous, and that concern other, diverse matters: the nature of human difference and inequality, competition among scholarly disciplines, or the competence and vision of a particular monarch's ruling group.

Differentiation: Registers, Communities, Variation and Change

Speech community, linguistic repertoire, variation, register and style are among the foundational concepts of linguistic anthropology. Adopted from earlier frameworks of research, they were redefined by the work of the 1960s. In the last twenty years they have been transformed once again in light of the notions of indexicality and metapragmatics/ideology. In any social group, images linking typical persons to typical activities and typical linguistic practices draw on culturally salient and elaborated principles of differentiation (e.g. presupposed notions of caste or occupation, folk theories of gender and personhood) that are often perceived by participants as necessary and inherent distinctions. These ideological principles – axes of differentiation – mediate between social and linguistic characteristics and orient the practices and relations of interactants. Speech communities and language communities are emergent effects built out of such axes of differentiation.

Linguistic variation often appears to speakers (and to analysts) as a reflection or diagram of social differentiation. A famous example is the finding by Labov and his students that phonological variables correlate with situational style and the socioeconomic status of speakers. The analytical task is to specify the ideological – or more precisely the semiotic – processes by which these correlations arise and become significant. Why and how do particular chunks of linguistic material coalesce into recognizable and nameable ways of speaking (registers) that gain significance as signs of particular populations, activities, settings, and are heard as appropriate to certain events. Furthermore, how is it that in any interaction, the expected correlations can be subverted or transposed, thereby signaling quite unexpected messages?

The extension of a Peircean theory of signs has been productive in approaching these issues. Linguistic features that form co-occurring clusters or registers are indexical of (point to) categories of speakers who regularly use them, or to situations and activity types in which the features regularly occur. But not all real-world co-occurrences form indexical signals. The co-occurrences must be noticed and formulated within some cultural or ideological system. To make such linkages and render them meaningful for speakers often requires extensive discursive efforts and the effects of media circulation. Another means of establishing meaningful indexicalities is through ritual and institutionalization. When both the ways of speaking and the people or activities are typified, schematized and conceptually linked, the result is a system of registers that evokes a system of stereotypes. Formulations of referents in minute-to-minute interaction rely on these associations. Registers often include not only linguistic material but also other signaling systems such as clothing, demeanor and gesture. Linguistic-forms-in-use that are thus ideologized as distinctive and implicating distinctive kinds of people can always be resignified, further ideologized (or misrecognized) as emblematic of other social, political, or moral characteristics in what Silverstein has dubbed multiple orders of indexicality.

Another of Peirce's sign relations – iconicity – is key in differentiation, according to Irvine and Gal (2000). Peirce distinguished between indexes that point to their objects and icons that share the qualities of their objects, for some interpretant (e.g. a theory or ideology). In sociolinguistic differentiation, there is always a *set* of contrasting indexes pointing to contrasting objects in a relation that Peirce would call diagrammatic iconicity. Furthermore, the indexical links between linguistic signs and speakers, characteristics or events are understood not simply as a cooccurence but a sharing of quality. When an index is thus perceived as an icon, the resulting sign is a Peircean 'rheme.' Essentialization is in part constructed semiotically, through the perception that the sign and the object are iconically linked. A system of such contrasts, salient at one level or scale can be projected, in a fractally recursive manner, onto other scales of social and linguistic relation, either broader or

narrower. This allows for the proliferation of the same or similar difference at greater and smaller scales. Social or linguistic aspects of the sociolinguistic scene that do not fit such systems of stereotypes are semiotically erased. That is, they are ignored, backgrounded and sometimes physically eliminated.

When a system of such indexical signals is the basis of social interaction, then participants can have fairly strong expectations about communication. Even if the participants do not share what is usually called a single language, they recognize the kinds of speech that signals different sorts of people and activities, and a speech community can be said to exist. Note the similarity to the Prague School's notion of *Sprechbund*. Since precolonial times, networks of exchange, commerce, travel and exploration have been creating speech communities that are diverse in social function, stability and extent. It is important to make an analytical distinction. Speech communities consist of people who can interpret each others pragmatic, indexical signals to varying degrees. Language communities are groups of people bearing loyalty to norms of denotational system. Usually the denotational form receives a name – English, Swahili, Taiap – and is imagined as bounded and separate from other comparable units. Language communities emerge as cultural system in the context of heterogeneous speech communities when difference in denotational practice is ideologized as significant. Thus contact and interaction – not isolation – produce distinct language communities.

Language communities, although always characterized by loyalty to code, are nevertheless culturally distinct. Sometimes a single person's speech is recognized as exemplary and aesthetically pleasing. In other cases the form of speech used in a certain setting or event (kiva, longhouse, oratory) is considered the model worthy of emulation. More common in the world today is the language community that is linked to a state system and oriented not to beauty but to standardized forms of correctness, monitored by language academies, school systems and grammar books. Named languages do not simply exist in the world. Through institutions they are constantly being made and reconstructed, their boundaries policed and defended. In the process of consolidation, standard languages often become gate-keeping devices in national labor markets, providing speakers who control them with increased access to jobs and other resources (Bourdieu, 1981). But the value of standard languages does not derive from such direct market activity; rather their market value depends on semiotic processes of differentiation.

Speakers who are incorporated into colonial empires through bureaucracy, trade, or conquest, but do not speak the language of the state, come to see their own linguistic practices through the eyes of the powerful center. Therefore, they come to see themselves relationally, as peripheral. For such populations, the switch in perspective produces novel self-understandings as 'minority' 'local' or 'indigenous.' In states organized as democratic and multicultural, legitimating one's indigeneity or minority standing requires at least partial adoption of the state's standardizing ideology. Whatever their own ideologies about linguistic practice, such populations must often produce a denotational code different enough from others to count as a 'language' of their own. For many decades, such 'local' languages were the special province of anthropological linguists, whose descriptions deliberately erased – as inauthentic – the contact languages and multilingualism that tied indigenous speakers to their neighbors and colonial rulers. Part of the problem is that Euro-American linguists' notion of language as morpho-syntax-with-sound pattern is often at odds with local definitions that focus on lexical co-locations, place names, prosodical features and textual organization. These differences acquire increased significance when indigenous languages are considered endangered. The question of what merits documentation becomes a highly consequential matter, argued by scholars, by courts, and among members of the language community. As Hill and others have shown, whatever counts as linguistic knowledge in indigenous communities often endows its owner with authority and access to local resources. The position of Euro-American linguists as experts and arbiters in these matters is rife with moral contradictions that have been a focus of professional writing in recent years.

The exploration of metapragmatics and language ideology has produced new approaches to language change. Change is often the unintended consequence of people attending to linguistic structures through the prism of their own language ideologies, limited as these are by cognitive contraints on awareness and sociopolitical framings of what is significant. Increasing linguistic differentiation occurs through patterns of schismogenesis among interacting speakers, or conversely through simultaneous use of genetically different denotational codes in codeswitching (Heller, 1988). Codeswitching itself become the focus of loyalty, thereby producing a new language community. Other processes of differentiation result in language obsolescence, or contrariwise in language revival and the creation of 'heritage' languages for diasporic populations (Dorian, 1989). Also common is the commodification of language or linguistic practice for touristic purposes and the concomitant 'ethnicization' of local denotational codes when they

co-exist with a standardized state language. In this process there are often structural changes in the local language that mark it as iconic of the group with which it is identified. Ideologies of 'modernity/tradition' 'male/female,' 'purity/dirt,' and presuppositions about typified emotional states, notions of self, and quite local political issues, all can mediate between the socioeconomic situations of speakers and the forms of language change they experience (Gal and Irvine, 1995). Ideological framings of difference penetrate significantly into grammar.

A semiotic analysis of differentiation has implications for the study of processes beyond linguistic practices. The tendency for nationalisms to recursively evoke internal divisions of the populace into foreign-natives vs. native-natives is well explained by the semiotics of differentiation. In colonial and imperial circumstances, details of cultural practices have been interpreted as evidence of the relative 'humanness' of conquered populations in contrast to conquerors. Projections of this kind are not presupposing indexes of existing features, but creative (performative) acts that bring into interactional relevance the very iconic similarities they seem to be merely describing. In yet another form of differentiation, speakers adopt the Goffmanian 'figures' of others. That is, they take on, for varying periods of time, the registers, objects and activities seen as iconic of others in acts of Bakhtinian mimicry, quotation, parody and/or admiring emulation. By attending to the semiotics of differentiation linguists study the dynamics of heteroglossic social orders.

Language and Thought

Whether and how grammatical categories influence habitual thought and 'perceptions of reality' are among the oldest concerns of anthropological linguistics/linguistic anthropology. They were first raised for European science by colonial exploration and contact with languages whose grammatical structures seemed exotic in relation to the patterns familiar from study of geographically more proximate populations. In one way or another such differences worried Boas, Sapir, and Whorf, and well before them inspired Humboldt, Herder and Condillac. The issue has continued to draw scholarly interest throughout the 20th century.

If one were to consider the social power to be gained from the ability to define social 'reality' – as in Gramsci's cultural hegemony, Foucault's discourse, Bourdieu's doxa – then this set of questions would parallel those raised in the rest of linguistic anthropology. Characteristically, however, studies of linguistic relativity have taken a narrower view of linguistic practices, and have considered neither power nor a socially located and mediating ideology. Positing a more direct relation between language and thought, they have studied psychological and cognitive processes in themselves. There is currently a reversal in this trend, however, bringing studies of linguistic relativity closer to the issues of identity formation, politics, conflict and social differentiation that characterize the rest of linguistic anthropology. Recent work suggests that issues of translation, register and interaction will become as important in studies of linguistic relativity as they are increasingly becoming in other areas of linguistic anthropology. Two reviews provide excellent guides to the state of research and its disputed history: Hill and Mannheim (1992) and Gumperz and Levinson (1996). It will suffice here to note some areas of consensus among scholars, before taking up three contested issues to give a sense of the debates and the way terms such as language and thought have been redefined.

These matters are agreed: First, linguistic relativity (or the so-called Sapir-Whorf hypothesis) is not a hypothesis to be 'tested' but an axiom or starting point for research. Grammatical categories, to the extent that they are obligatory or habitual and relatively inaccessible to speakers' consciousness form a privileged location for reproducing cultural and social categories because they constrain the ontology taken for granted by speakers. There is no assumption about the coherence of entire 'world views' in this as in any other corners of anthropology. Second, although evidence of universals in human cognition has been thought to undermine a search for language-specific cognitive phenomena, all researchers acknowledge both. The interesting questions concern the relative strength, nature, sequence and role of universals vs. cultural-linguistic specificities and what those specificities might be. Third, it follows that Whorfian effects exist. This is hardly surprising given the discussions above about creative indexicality and projections. Finally, research priorities have shifted during the 20th century. Due in part to the Chomskyan 'rationalist' program in linguistics, the cognitive turn in psychology, and the empirical results of Berlin and Kay's (1969) research on color terminology, universals took center stage in the 1970s. Currently, there is a renewed interest in Whorfian effects from a number of different perspectives.

Turning now to contested issues, the first concerns the category 'grammar.' Whorf proposed that languages differ in the grammatical **analogies** they make. By handling substantively different lexicon within the same grammatical frame, they invite speakers to treat the otherwise different items in a similar way. Thus, English treats days, years and months not as cyclical

events but with the same grammatical devices as ordinary object nouns. English speakers expect – by unconscious analogy – to count time in the same way as they count tables. They ask about the substance out of which days are made, on the analogy of wood as the substance out of which tables are made. Hence the objectification of time as a substance. Such analogies are unquestioned background assumptions. They become apparent to analysts if one analogy system is compared to another that provides different hidden parallels. Careful methodology is fundamental here: when two systems are compared, neither can be taken as the standard or metalanguage for the other.

Some theorists suggest that the privileging of morphosyntax and its effect on semantic categories is misplaced, in a world of multilingualism. Friedrich proposed instead that the tropic or 'poetic' aspects of language, inflected by ethnopoetics, will differ most across cultures. (This echoes cognitive linguists' claims that habitual metaphors structure thought.) Similarly, if the poetic form of narration changes during language shift, there is a loss of a distinct cultural pattern for organizing experience. Others counter that narrative organization signals merely a difference in the way that experience is packaged for the purpose of talk, and is not necessarily reflective of cognition. This formulation runs into trouble, however, if people must use obligatory linguistic categories to encode experience in order to plan for future recountings.

A second set of arguments starts from experimental or cognitive psychology and the presumptive priority of universal cognitive processes. For some, linguistic relativity is not an issue because they assume language and cognition to be isomorphic, with thought as 'inner speech.' Linguistic relativity is also irrelevant for domains assumed to be unmediated by language: physical, musical or craft skills that are thought to be coded in somatic schema. Theories about universals of thought derive also from the Kantian tradition that takes categories of time, space and cause as the fundamental grounds of human reasoning. For many domains, there are also likely to be universal constraints imposed by the nature of the domain itself, and the specialized anatomical and neurophysiological adaptations of humans to a concrete world: wavelength for color; gravity in the case of space. Even in the realm of language there might be universals of structure or lexical organization. What does linguistic specificity add to such universals? Levinson suggests that in the case of space and possibly many other domains, linguistic relativity is still powerfully involved. Universals substantially *underdetermine* the possibilities of conceptual solutions to describing spatial arrangements.

A third controversy takes up Hymes's early suggestion that there is a linguistic relativity of language use as much as of linguistic structure. Populations differ in the genres and events they recognize. Interpretations that participants derive from utterances are always dependent on sociocultural context. Thus, the fit between language and thought is mediated by habitual practice; social interaction and cultural beliefs (ideologies) about the everyday world. For instance, deictics of space are found in all languages. Nevertheless, as Hanks argues, they encode culturally specific information, and they map social and experiential fields, not objective spaces. Thus, cultural schema of several kinds mediate between the use of a deictic term and its proper interpretation. Furthermore, these frames and schema are not always equally available to all speakers in a community. A linguistic division of labor is often evident, as is the consequent necessity to negotiate meanings between interactants. Clearly, this brings to the study of linguistic relativity questions of indexicality, entextualization and ideology. For the study of linguistic relativity the implications are significant: There might be as much variation between speakers in their access to alternate perspectives and theories as there is across 'cultures.' Furthermore, distinguishing between 'language' 'culture' and 'thought' is at best a rough methodological tactic. The object of investigation for linguistic anthropology, in current practice, is exactly 'culture' as a process that is simultaneously semiotic, interactional and linguistic.

Linguistic decolonization describes both the actions taken in postcolonial contexts to undo the social, political, and cultural effects of the dominance of colonial languages and a philosophical challenge to the Western language ideologies that underpinned the colonial project and that have persisted in the postcolonial period. A wide view of 'colonization' includes not only the classic cases of Western expansionism but also 'internal colonialism' involving indigenous and minority populations within the nation-state (*see* **Minorities and Language**). We can speak of linguistic decolonization in a multitude of contexts, ranging from new state formation in Africa and Asia and the former republics of the Soviet Union to indigenous language planning in the Pacific, North and South America, to minority language movements in Western Europe. Given this vast scope, no pretense will be made here to cover all possible contexts and the vast literature in language planning and postcolonial studies; rather the aim is to outline some of the common features and challenges of documented processes of linguistic decolonization and what they have to say about language ideologies and policies in general (*see* **Linguistic Rights**).

Linguistic decolonization always takes place within a nationalist project: either as an element of new nation-building, or as an effort to legitimate languages and identities that were unrecognized or actively suppressed under colonialism. Linguistic decolonization projects have thus been preoccupied with redressing linguistic inequality and cultural oppression in the public sphere, particularly in education and in official/governmental life, by replacing

Linguistic Decolonization

A Jaffe, California State University, Long Beach, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Linguistic decolonization describes both the actions taken in postcolonial contexts to undo the social, political, and cultural effects of the dominance of colonial languages and a philosophical challenge to the Western language ideologies that underpinned the colonial project and that have persisted in the postcolonial period. A wide view of 'colonization' includes not only the classic cases of Western expansionism but also 'internal colonialism' involving indigenous and minority populations within the nation-state (*see* **Minorities and Language**). We can speak of linguistic decolonization in a multitude of contexts, ranging from new state formation in Africa and Asia and the former republics of the Soviet Union to indigenous language planning in the Pacific, North and South America, to minority language movements in Western Europe. Given this vast scope, no pretense will be made here to cover all possible contexts and the vast literature in language planning and postcolonial studies; rather the aim is to outline some of the common features and challenges of documented processes of linguistic decolonization and what they have to say about language ideologies and policies in general (*see* **Linguistic Rights**).

Linguistic decolonization always takes place within a nationalist project: either as an element of new nation-building, or as an effort to legitimate languages and identities that were unrecognized or actively suppressed under colonialism. Linguistic decolonization projects have thus been preoccupied with redressing linguistic inequality and cultural oppression in the public sphere, particularly in education and in official/governmental life, by replacing

all or part of the colonial language's public functions with one or more local, indigenous, or minority languages.

Projects of linguistic decolonization are thus profoundly shaped by dominant ideologies of language and nationalist ideologies about how language is related to cultural and political identities. These ideologies include the central premises that languages are 'natural' and clearly bounded entities that map onto equally natural human boundaries; that there is an essential or primordial link between a single language (conceived of as the 'mother tongue') and a single/unitary identity (either personal or collective).

A combination of social, ideological, and pragmatic issues complicate the process of linguistic decolonization and its goals of democratization and cultural legitimation for previously colonized groups. On the practical level, in postcolonial contexts it is rare that linguistic decolonizers have access to all the material and political resources needed to replace the status and functions of the colonial language in all domains. It is also the case that both local and global political economies of language are resistant to challenges to those powerful, former colonial languages. This is because those languages often still constitute social and political capital at the local level, where they can be used by local elites to legitimate their social positions.

Second, those languages (particularly English) have currency in new, global markets, motivating postcolonial social actors to embrace dominant language education in search of economic mobility despite the cultural value of schooling in the minority or indigenous language.

It is also the case that when minority or indigenous languages are 'developed' in the image of the colonial languages they replace, language planning efforts (normalization, officialization, standardization, codification) have the potential to create new forms of linguistic hierarchy. First of all, language planning policies may favor particular languages or dialects and thus their speakers. In some cases, those hierarchies are accepted by the population, to the benefit of particular speakers. In other cases, this political dimension of language policy ends up creating a permanent crisis of legitimacy that prevents postcolonial language planners from reaching any consensus. More generally, the introduction of minority or indigenous languages in the spheres of literacy and education inevitably creates a divide between 'good/pure' and 'bad/mixed' codes and validates new forms of expert linguistic knowledge owned by a minority.

With respect to linguistic purism in postcolonial contexts, two points can be made. First, it is an outcome of dominant ideologies of authoritative language (*see* **Power and Pragmatics**). Second, as a result of contact with the dominant language, both the form and use of the dominated language are inevitably 'mixed' and therefore stigmatized, once 'high' forms of that language are introduced. The issue of linguistic purism highlights the difficulty of resisting or challenging the single language/single identity premise of the nationalist project. At the political level, agents of linguistic decolonization are often forced to legitimate noncolonial languages in dominant terms because those terms are imposed by powerful gatekeepers. In addition, there is the question of the 'colonized mentality': the fact that the validity of dominant ideologies of language, including the denigration of nondominant languages, has often been internalized by the general population. Postcolonial linguistic agents are often faced with a double-bind: if they use the colonial language, they are seen as traitors to their cultural/ethnic group; if they use the dominated language, their voice has a more limited power and reach (*see* **Pragmatics: Linguistic Imperialism**).

Truly radical linguistic decolonization projects would thus have to challenge the fundamental premises of dominant linguistic and cultural ideologies and practices. These radical forms of resistance involve the legitimation of plural or hybrid linguistic forms, practices, and identities, including the appropriation and reworking of colonial languages. This kind of linguistic decolonization is rare in the public sphere, although it can be seen in some indigenous education projects and is more noticeable in domains of artistic, creative linguistic practice.

Linguistic Ethnonationalism

The scholarly treatment of linguistic ethnonationalism is intimately linked to the question of the origins of the nation. A main division in scholarship on nationalism, between those who conceive the nation as an entirely modern phenomenon and those who trace its roots further back in time, has also resulted in contrasting positions regarding the role of language and linguistic practice in the rise of the nation. In the European context, proponents of the latter position have tended to treat linguistic difference as one of the principal markers of preexisting 'ethnic' difference that later developed into full-fledged nationhood in the 18th and 19th centuries. Anthony Smith (1989), for example, described awareness of linguistic boundaries and of sharing a vernacular language with emerging literary traditions as one of the features of 'ethnic cores' established in the premodern period, which provided a base for modern nationalism later on. Josep Llobera has argued that in the case of the territories later developing into England, France, Germany, Italy, and Spain, a sense of nationhood, even if restricted to a small part of the population and varying in salience among those territories, was already in place in the late Middle Ages. These early notions of nationhood also rested in part on the sharing of what were identified as common vernacular languages (Llobera, 1994). In contrast, modernists such as Benedict Anderson and Ernest Gellner categorically reject continuities between premodern forms of political identification and modern nationhood, nor have they treated premodern apprehensions of linguistic difference as significant for the constitution of modern nations. Instead, for them the importance of language and linguistic practice in the creation of modern nationhood lies above all in their integrative functions in processes of vernacular standardization and mass communication through print, a line of inquiry initially associated with Karl Deutsch (1953). There is little doubt that a concept of the nation existed in parts of Europe before the 18th century, as for example in the case of Spain, where in the early 17th century nationhood was already explicitly linked to the concept of a distinct vernacular language (Woolard, 2004). However, both modernists and those insisting on medieval or early modern origins of the nation tend to agree that nationalism as a political ideology demanding a form of popular sovereignty rather than a dynastic polity cannot be traced further back than the 18th century, and this also

Linguistic Ethnonationalism

The scholarly treatment of linguistic ethnonationalism is intimately linked to the question of the origins of the nation. A main division in scholarship on nationalism, between those who conceive the nation as an entirely modern phenomenon and those who trace its roots further back in time, has also resulted in contrasting positions regarding the role of language and linguistic practice in the rise of the nation. In the European context, proponents of the latter position have tended to treat linguistic difference as one of the principal markers of preexisting 'ethnic' difference that later developed into full-fledged nationhood in the 18th and 19th centuries. Anthony Smith (1989), for example, described awareness of linguistic boundaries and of sharing a vernacular language with emerging literary traditions as one of the features of 'ethnic cores' established in the premodern period, which provided a base for modern nationalism later on. Josep Llobera has argued that in the case of the territories later developing into England, France, Germany, Italy, and Spain, a sense of nationhood, even if restricted to a small part of the population and varying in salience among those territories, was already in place in the late Middle Ages. These early notions of nationhood also rested in part on the sharing of what were identified as common vernacular languages (Llobera, 1994). In contrast, modernists such as Benedict Anderson and Ernest Gellner categorically reject continuities between premodern forms of political identification and modern nationhood, nor have they treated premodern apprehensions of linguistic difference as significant for the constitution of modern nations. Instead, for them the importance of language and linguistic practice in the creation of modern nationhood lies above all in their integrative functions in processes of vernacular standardization and mass communication through print, a line of inquiry initially associated with Karl Deutsch (1953). There is little doubt that a concept of the nation existed in parts of Europe before the 18th century, as for example in the case of Spain, where in the early 17th century nationhood was already explicitly linked to the concept of a distinct vernacular language (Woolard, 2004). However, both modernists and those insisting on medieval or early modern origins of the nation tend to agree that nationalism as a political ideology demanding a form of popular sovereignty rather than a dynastic polity cannot be traced further back than the 18th century, and this also

applies to forms of nationalism drawing on perceptions of linguistic difference as a justification for popular sovereignty.

The first comprehensive formulation of linguistic ethnonationalism is commonly traced to Herder's critique of Kant's transcendental philosophy of subjectivity. According to Herder (1968), intellectual production and human subjectivity are not to be understood as based on a putatively universal pure reason but as grounded in and created out of particular linguistic traditions, which constitute humankind as a plurality of 'peoples.' Accordingly, the status of a group as a 'people' with a claim to nationhood is upheld by cultural difference, which is inseparably linked to a particular linguistic tradition. The 'spirit' of a nationalized 'people' is thus both expressed and shaped through cultural creativity necessarily bound to the use of a certain language. Herder claimed that language is not a transparent medium of cultural production, but argued that the particular characteristics of a linguistic variety or linguistic tradition have a profoundly shaping impact on the cultural life of a 'people.' Thus, according to Herder, language necessarily mediates cultural traditions not in constituting a neutral means of expressing them and conveying them to others, but in the sense of playing a productive role in cultural life and leaving an indelible imprint of its particularities on everything it cocreates and mediates.

This formulation has been extremely influential in the formation of German nationalism and other nationalisms of central and eastern Europe, and continues to inspire nationalist ideologues in a wide range of locations today. However, it is precisely the inevitability of the link suggested by Herder between a particular linguistic tradition and a particular sense of nationhood, which has the effect of naturalizing language-based nationhood, that has been widely rejected among scholars of nationalism, even by those insisting on premodern origins of the nation. Instead, the way apprehensions of linguistic difference have constituted and legitimized claims to nationhood has been shown to be a historically contingent process and subject to dynamic cultural construction and contestation. However, scholars have differed considerably in how much latitude they have assigned to such processes of construction. Another important division in approaches to linguistic ethnonationalism is between those emphasizing politicized images of linguistic belonging and difference as creative forces in the rise of nationalism since the 18th century versus those authors privileging the role of language in nationalism in its functional roles in modern systems of mass communication.

'Modernist' Theories of Language and Nationalism

Ernest Gellner's and Benedict Anderson's approaches to nationalism tend to stress the latter, 'modernist' position. For Gellner (1983), the emergence of the nation is a product of industrialization in the modern world. In order for industrial civilization to be possible, the multitude of local cultural and linguistic particularities characteristic of agrarian societies has to be superseded by large-scale cultural and linguistic uniformization. In particular, the spread of modern standardized vernacular languages protected by state-sponsored educational systems is described by Gellner as functionally necessary for the workings of industrialization. Nationalism emerges as a new ideology serving an integrative function for the larger social aggregates formed by industrial processes of production as well as vernacular literacy and mass communication, which crucially underpin them. Thus, nations are modern inventions, and can only arise under conditions of industrialization, while the cultural contents of nationalisms and the kind of standardized languages they are based on are ultimately arbitrary. Benedict Anderson depicted a related scenario in explaining the rise of nationalism, in which language also plays a central role (Anderson, 1991). Anderson shifted the focus from industrialization to print capitalism in arguing that the circulation of books, newspapers, and pamphlets in vernacular languages in Europe and its settler colonies in the Americas since the early modern period led to the creation of 'imagined communities' of nations transcending face-to-face interaction in new circuits of mass mediated communication. Thus, nations are essentially conceived as reading publics separated from each other by the use of different print vernaculars.

The association of ethnolinguistic nationalism with the relative decline of sacred languages and the rise of standardized vernaculars is a common theme in these approaches, postulating a close relationship between language and nationalism while explaining the latter as the result of a transformation of patterns of mass communication under conditions of capitalism or industrialization. In this context, both Anderson and Gellner tended to treat the spread of standardized vernaculars more as a matter of functional and administrative convenience rather than a political process driven at least in part by ideologies of linguistic difference. In Anderson's view, language is important because print languages function as channels of communication regimenting access to and exclusion from the national community, while constituting a shared medium through which ideas of the nation can be disseminated. Both Anderson and Gellner

tended to downplay how linguistic ethnonationalism privileges language as an ideological site where the imagination of the nation is produced and boundaries of national communities are conceived and formulated. The ways in which language, especially standardized vernacular language, emerges as an ideological prism through which membership of such communities is defined and justified are not just confined to the communicative separation of different reading publics or social aggregates of industrialism due to vernacular linguistic difference. Also, vernacular standardization has often been not only a matter of administrative convenience but also an eminently political process, mediating membership in and exclusion from national communities. Anderson, for example, described the rise of standard French and English as relatively unplanned and driven by 'pragmatic' reasons (1991: 40–42), also stating that in 19th-century France and England, "for quite extraneous reasons, there happened to be, by mid-century, a relatively high coincidence of language-of-state and language of the population" (1991: 78). However, the political and military events behind such coincidence need also to be addressed in an understanding of linguistic ethnonationalism. As the work of Eugen Weber shows, a highly ideologized state-driven process of linguistic unification and suppression of regional languages was still ongoing in late 19th-century France, as "the Third Republic found a France in which French was a foreign language to half its citizens" (Weber, 1976: 70). That is, the spread of standardized vernaculars was also furthered through coercion against those now deemed minorities or foreigners in a national community conceived through the lens of political representations of linguistic difference. Thus, Anderson's important work on the rise of the nation as a consequence of new forms of mass mediated communication needs to be complemented with a stronger emphasis on politically charged ideas of linguistic differentiation as motivating forces in the construction of new national communities.

Linguistic Anthropological Approaches

The relationship between linguistic practice and senses of nationhood has been conceived in different terms in linguistic anthropology. Dell Hymes and John Gumperz argued in the 1960s that the use of a linguistic variety as a shared medium of communication does not necessarily turn those sharing a linguistic code into a community or ethnic unit. This tradition of skepticism regarding integrationist approaches assigning shared standardized vernaculars a key role in the formation of modern nations puts contemporary linguistic anthropology at odds with the revival of the assumption in contemporary theories of nationalism that 'shared language' results in the creation of groupness.

Instead, linguistic anthropologists have emphasized the importance of ideological mediation in establishing a link between language and nationality. In a research paradigm of 'language ideology' (Silverstein, 1979; Woolard and Schieffelin, 1994) linguistic anthropologists have described how such politically charged ideas about language and its users have resulted in the projection of national communities (Gal, 1993; Silverstein, 1996; Schieffelin *et al.*, 1998; Errington, 2000). While concurring with the 'modernist' approach to nationalism in treating nations as dynamically constructed cultural phenomena of relatively recent origin, they also extend this perspective to the construction of languages and linguistic communities. Linguistic varieties and linguistic communities are not simply present 'on the ground' ready to be made use of by modern systems of mass communication to generate a sense of shared nationhood, they are frequently themselves the outcome of scholarly and administrative construction informed by nationalist ideologies (Gal, 1995). That is, linguistic anthropologists have insisted that vernacular standardization is a political process, which is often the result of the rise of the nation rather than merely its precondition.

Urla's study of Basque linguistic ethnonationalism is a case in point, not only showing that linguistic standardization of Basque was in part motivated by an emerging Basque nationalism, but also that a focus on Basque became central to Basque nationalism precisely because many of those considered members of a Basque nation turned out to have little knowledge of it. The sense of a language being 'threatened' can thus emerge as a catalyst for linguistic ethnonationalism, and the language portrayed as an emblem of the nation may not always be the language employed in the systems of mass communication used for national mobilization and the creation of a national public (Urla, 1988, 1993).

The latter point is especially important in assessing approaches to linguistic ethnonationalism proposed by political scientists explaining it as a reaction to blocked social mobility and political exclusion due to imposed linguistic barriers in state institutions, as Inglehart and Woodward (1972) did for the 19th-century Austro-Hungarian monarchy and, more recently, DeVotta (2004) did for Sri Lanka. According to this interpretation, linguistic ethnonationalism arises when members of a group sharing a vernacular language, often a minority or otherwise subordinate group within a state, face discrimination when the state they live in imposes another linguistic variety

as the sole medium of education and administration. As a counterreaction, influential members of the group start to agitate for a separate nation-state whose institutions would function in their vernacular. The new nation-state to be created would thus provide the opportunities for social mobility that are denied by the institutions of the state that members of such a minority have so far lived in. However, this model does little to account for frequently widespread bi- or multilingualism among linguistic minorities, nor for those scenarios where knowledge of and especially literacy skills in the dominant language of state are more common among members of a minority than corresponding skills in the minority language promoted as the emblem of a new nation. As Urla wrote about the origins of Basque linguistic ethnonationalism in the late 19th century, "when Sabino Arana y Goiri, the son of a Bilbao industrialist and founder of the PNV (Partido Nacionalista Vasca, Basque Nationalist Party), declared Euskera to be one of the defining features of the Basque nation, the first thing he had to do was to learn it himself" (Urla, 1993: 822). The Basque case exemplifies such a situation where bilingual and in many instances predominantly Spanish-using members of a Basque middle class did not face linguistic exclusion in a previously Spanish-only system of education and administration. It also does little to explain why, as in the Basque and the Austro- Hungarian cases, precisely those multilingual urban intellectuals with a full command of the dominant language of state were the initiators of separatist linguistic ethnonationalisms rather than the monolingual rural populations who were often portrayed as exemplary members of the new nations to be created.

In other words, linguistic ethnonationalism needs to be taken seriously on its own terms, as the imagination and construction of communities through images of language and linguistic difference. It thus has to be understood as a politically creative force in its own right and as a form of regulating social life, and not be treated as the epiphenomenon of an essentially nonlinguistic political process of competition over scarce resources and state power. Also, the national boundaries thus created through ideologies of language cannot always be reduced to the boundaries between different reading publics, which, according to Anderson, rest on the "fatality of human linguistic diversity" (Anderson, 1991: 43). It is important to realize that linguistic ethnonationalism as a social and political force has frequently reshaped regimes of linguistic diversity by mapping social and political differentiation on perceived linguistic differences in novel ways. For some scholars, this circumstance has been nowhere more clearly illustrated than in European attempts at linguistic description and reorganization in the colonial world.

The Colonial Context and the Worldwide Spread of Linguistic Ethnonationalism

An important question in assessing the global spread of Herderian ideologies of linguistic ethnonationalism is whether the thesis of the modularity of nationalism generally postulated by Anderson (1991: 4) can also be extended to linguistic ethnonationalism. As such, the question of linguistic ethnonationalism in colonial and postcolonial contexts is bound up with wider debates about whether colonial and postcolonial nationalism exhibits irreducible differences from the European–American and European nationalisms that were its first historical instances, as, for example, suggested by Partha Chatterjee (1993). European colonial governments as well as other European nonstate actors active in the colonial world, such as missionary societies, embarked on extensive projects of identifying, describing, classifying, and standardizing vernacular languages of their subject populations, which frequently led to large-scale transformations of the linguistic and political situation in colonies (see also Errington, 2001). One of the main ways in which such colonially induced transformations came about was the introduction of new ideas of linking social to perceived linguistic differentiation. In particular, the Herderian principle of linguistic ethnicity, according to which a population is constituted as an ethnic group by virtue of sharing a common vernacular language, informed such linguistic classificatory work and language construction in the colonies. A second assumption derived from the European trajectory of linguistic ethnonationalism also had a large impact on the colonial reorganization of linguistic landscapes: the idea that a vernacular linguistic tradition necessarily has a standard form. Wherever this standard was not readily discernible, the task was to find and identify the 'real' standard form of vernacular varieties, which inevitably resulted in language construction. Colonial India provides a good example of how both these tendencies set off political processes whose outcomes did not always conform to the intentions of the colonizers. For example, the search for a 'language of command' for northern and central India by scholars of Fort William College in Calcutta led them on a search for the 'real Hindustani,' knowledge of which was expected to facilitate the rule and administration of large parts of India. Undeterred by the initial puzzlement of their Indian subjects, whose visions of linguistic differentiation were largely dominated by an opposition of standardized sacred (Sanskrit, Arabic) and imperial (Persian [Farsi])

languages on one hand, and largely unstandardized local vernacular varieties on the other, colonial scholars and administrators constructed a standard Hindustani. They thus contributed to the emergence of the Hindi–Urdu conflict, the partition of India, and the creation of Modern Standard Hindi as a national language of India later on (Cohn, 1985; Lelyveld, 1993). In India, the introduction of the Herderian principle of linguistic ethnicity through the colonial mapping of vernacular languages was institutionalized as an alternative to previously established modes of conceiving linguistic differentiation above all in terms of links between ranked endogamous descent groups (*jati*) and linguistic varieties in eminently local contexts (Washbrook, 1991). This also turned out to have important consequences for postcolonial politics. Linguistic ethnicity in the end provided the basis for political claims for distinct 'homelands' for users of particular standardized linguistic varieties, which resulted in a reorganization of federal states along assumed vernacular linguistic lines in postcolonial India.

One of the ironies of the global spread of linguistic ethnonationalism is also that in many instances this new political principle originated in colonial attempts at linguistic classification and language construction, which were intended to facilitate and legitimate colonial rule, only to provide a platform for the emergence of anticolonial nationalisms later on. The colonial creation of a standard Malay, for example, not only provided a unified administrative language for a large and populous archipelago with great linguistic diversity, it also facilitated the emergence of an anticolonial public among local elites, who subsequently used the new language, now labeled Indonesian, against their Dutch colonizers, turning it into a key emblem of a newly imagined Indonesian nation whose citizens were expected to become users of the language (Errington, 2000).

Related processes were at work in colonial Africa, where the construction of standardized vernaculars for missionary or administrative purposes often led colonial administrators to assign populations distinct 'ethnic' or 'tribal' identities on the basis of such newly defined linguistic affiliations. These practices had important political consequences once such classifications became established and accepted by large numbers of those subjected to such colonial mapping of social and political difference (Harries, 1988; Irvine, 1993; Meeuvis, 1999). Linguistic anthropologists have seen in these colonial policies particularly illustrative instances of the creative power of linguistic ideologies, where politically charged images of language and linguistic differentiation motivated the creation of new social aggregates with claims to ethnic and national identities (Irvine and Gal, 2000).

Nevertheless, it would be inadequate to speak of a simple imposition of European assumptions of linguistic ethnicity and linguistic ethnonationalism by colonial actors on colonized populations, since the outcome of colonial vernacular language standardization and language construction often resulted in cultural forms profoundly different from European understandings of linguistic ethnonationalism. Sumathi Ramaswamy's study of Tamil language-focused nationalism provides a vivid analysis of how colonial perspectives interacted with local visions of language and group identities in unforeseen ways (Ramaswamy, 1997). In taking up European characterizations and comparative analyses of Tamil, Tamil activists linked the Herderian idea of linguistic ethnicity to established notions of devotional practice. They thus arrived at a vision of the Tamil language as a female deity, *Tamiltay*, and Tamils as a family of faithful children determined to protect a language simultaneously conceived as deity and mother. Ramaswamy has argued that this colonial and postcolonial form of linguistic ethnonationalism should better be understood as 'language devotionalism.' The Tamil scenario provides a compelling case for reexamining and refining Anderson's thesis of the modularity of nationalism and its language-based aspects. Ramaswamy's work suggests that the spread of nationalism in the colonial and postcolonial worlds should be conceptualized as the result of complex articulations of European understandings of nationality and linguistic belonging with precolonial traditions of establishing links between linguistic practice and social identifications rather than a directly modular adoption of European forms of belonging.

Contemporary Movements of Language Renewal and Linguistic Ethnonationalism

Linguists have recently voiced concern about the increasing loss of linguistic diversity in the contemporary world, seeking to mobilize public opinion in Western countries in favor of supporting the continued use of those languages with often smaller numbers of users undergoing language shift. In doing so, they have often drawn on discourses of biodiversity, literally describing these languages as 'endangered' species which need to be saved from extinction. Another theme in professional discourses of 'endangered' languages is cosmopolitan concerns about the necessity to prevent the loss of intellectual production, feared by many as a consequence of the eventual demise of many lesser-used languages, which

would benefit humanity in its entirety. However, actual investigation of the social and political contexts of more successful instances of reversing language shift shows that such cosmopolitan views about the necessity to preserve knowledge for 'humanity' or the benefits of linguistic diversity portrayed as equivalent to those of biodiversity have played only minor roles. Instead, language activists have often rallied in favor of continued use of a language in response to perceived threats to positively valued forms of groupness, often cast in ethnic or national terms. Thus, such movements for reversing language shift have frequently drawn on the Herderian theme of a necessary link between a particular linguistic tradition and the constitution of a population as an ethnic group with the ethnonationalist claims often implied in a politics of recognition.

Furthermore, such contemporary language renewal movements also represent an interesting parallel to earlier scenarios of linguistic ethnonationalism in their extensive use of mass-mediated communication, now also in its electronic and digital forms (Eisenlohr, 2004). First, for example, in digitally recording linguistic practice in an 'endangered' language for purposes of documentation and instruction, language activists and linguists also engage in the production and archiving of electronic artifacts in a way that recalls earlier modern forms of storing and displaying the heritage of a 'people,' such as the museum and the archive (Silverstein, 2003). Such techniques of collecting and curating have in turn been closely linked to the history of the rise of nationalism, the display and archiving of 'traditional' objects and art forms being one of the ways of producing the imagined community of the nation (Anderson, 1991). In creating and selecting documented linguistic material for use in projects of language revitalization, language activists and supporting linguists often define the linguistic 'tradition' of the people who are interested in the renewal of a language they identify as 'theirs.' They thus play a key role in constructing boundaries of communities through representations of linguistic difference in a manner recalling the roles played by lexicographers, folklorists, and grammarians in 19th-century European nationalism (Anderson, 1991, Hobsbawm, 1990).

Second, in their attempts to create mass-mediated publics for users of lesser-used languages, language activists have often sought to promote the use of such varieties by replicating the creation of new forms of community and political solidarity often associated with the circulation of mass-mediated discourse in a shared vernacular. On the other hand, it is not just that new electronic practices of mass mediation are ways of disseminating and circulating discourse differently, but also, in the eyes of its consumers, mediated discourse is often invested with particular qualities since such practices of mass mediation are frequently associated with notions of modernity and sophistication. Language activists frequently draw on such evaluations of electronically mass-mediated discourse by seeking to transform valuations of a lesser-used language by using it on television, radio, CD-ROM, DVD, and the Internet. Thus, the use of languages to be revitalized in electronic media is not only aimed at the creation of new publics but also at changing images of the language among its users through a demonstration that the linguistic variety and its users are indeed part of a modern world.

Nevertheless, the example of language activism on behalf of lesser-used languages shows that linguistic ethnonationalism can also focus on 'heritage' or 'ancestral' languages, which are only rarely used in everyday interaction or in practices of literacy, as is for example the case among several Native American groups in the United States and Canada. Such scenarios, not infrequently found among users of a language in advanced stages of language shift, demonstrate that given the appropriate ideological background, the particular linguistic variety adopted as an emblem of ethnonationality need not always be related to those varieties used either in vernacular practice or in mass mediation of discourse.

When attempting to model and to understand the complexity of natural language, linguists typically have recourse to features. At the simplest level, features are used to factor out common properties. We can recognize a feature NUMBER, with the value 'plural,' as present in forms like *books, loaves, men, oxen*. Using a feature captures the idea that the plural items are in some sense the same (for example, for agreement purposes, since all take *these* rather than *this*) even though number is realized differently. Other examples include TENSE (present, past, etc.) and PERSON (1st, 2nd, 3rd). Features show consistency across entities, and to some extent across languages. They have proved invaluable for analysis and description, and have a major role in contemporary linguistics, from the most abstract theorizing to the most applied computational work. Our examples have been of morphosyntactic features. Features may also be phonological (specifying, for example, the height or backness of a vowel), morphological (specifying the inflectional class of an item), syntactic (for syntactic categories such as V or N) or semantic (such as ANIMACY).

When attempting to model and to understand the complexity of natural language, linguists typically have recourse to features. At the simplest level, features are used to factor out common properties. We can recognize a feature NUMBER, with the value 'plural,' as present in forms like *books, loaves, men, oxen*. Using a feature captures the idea that the plural items are in some sense the same (for example, for agreement purposes, since all take *these* rather than *this*) even though number is realized differently. Other examples include TENSE (present, past, etc.) and PERSON (1st, 2nd, 3rd). Features show consistency across entities, and to some extent across languages. They have proved invaluable for analysis and description, and have a major role in contemporary linguistics, from the most abstract theorizing to the most applied computational work. Our examples have been of morphosyntactic features. Features may also be phonological (specifying, for example, the height or backness of a vowel), morphological (specifying the inflectional class of an item), syntactic (for syntactic categories such as V or N) or semantic (such as ANIMACY).

The notion of feature emerged in discussions on the nature of the phoneme, particularly by Trubetzkoy and Jakobson, and this research was crystallized in Jakobson *et al*. (1952). In the 1960s, features were given an important place in lexical semantics (Katz and Fodor, 1963), in syntax (Harman, 1963; Katz and Postal, 1964; and Chomsky, 1965) and in morphology (Matthews, 1965). A major development was Generalized Phrase Structure Grammar (Gazdar *et al*., 1985), which brought together the linguistic work of Stockwell, Schachter, and Partee with the formal work of Martin Kay in an attempt at a fully articulated theory of features.

In subsequent years, features have taken on an even greater role, yet conceptualization has lagged behind. The notion of default has been employed widely in linguistics, but with varying interpretations (distinguished in formal terms in Fraser and Corbett, 1997). In Lexical Functional Grammar and Head-Driven Phrase Structure Grammar, work on unification is central to the use of features. In Government and Binding Theory and Minimalism, the notion of checking performs a similar but significantly different role (see, for example, Chomsky, 2000). Even though the theoretical machinery available has been extended by the introduction of typed feature structures (see Carpenter, 1992), we still lack a convincing account for some basic phenomena. However, there are encouraging moves to bring formal accuracy together with a range of interesting data, to bring us closer to an adequate theory of linguistic features.

Pierre Bourdieu's (1981) concept of habitus denotes a modality, which enables the individual to act routinely as well as creatively and innovatively. Central to Bourdieu's theory is the attempt to describe the dynamic relationships between the structural conditions of an individual existence, the individual's activities as a product of socialization under these conditions and the open-ended yet strictly limited capacity of the individual for action. In the process of socialization (*see* **Socialization**), a system of permanent dispositions is created in the individual, including sensitivity as one prerequisite for personal development. This system of dispositions and sensitivity is a necessary precondition for successful social activity.

Bourdieu emphasizes a circularity between 'structure,' 'habitus,' and 'practice.' Habitus functions as an awareness-matrix, an action-matrix, and a

thought-matrix for the individual; however, it does not alone determine behavior. A habitus is acquired under a certain set of social conditions, which Bourdieu calls 'objective structures.' To these belong the existential requirements, which characterize and define a social class. A habitus therefore is generated and regenerated by the specific objective structures of a class, and at the same time define and redefine, generate and regenerate the lifestyle and practice of its members. Bourdieu describes this circularity as follows: habitus function as "structured structures, which are suitable to function and work as structuring structures" (Bourdieu, 1979: 167). Implicit in a habitus is a tendency toward self-stabilization – despite the fact that socialization is not completed until death. New experiences are integrated in a habitus that leads to its constantly changing form while remaining relatively stable.

The term 'linguistic habitus' thus refers to the set of dispositions in the field of language: to a person's notion of linguistic 'normality' and of 'good' language, to a society's notion of 'proper' ways of language behavior, of 'legitimate' language variations and practice. The term does not describe language as a means of communication in a narrow sense, but refers primarily to the symbolic relations and signs by which language becomes a medium of power. Gogolin (1994) defines the monolingual habitus, which is common to the classical European nation states as an example of a linguistic habitus. In the process of their foundation in the 18th and 19th century, the basic and deep-seated belief was created that monolingualism is the universal norm for an individual and for a society (cf. Hobsbawm, 1990). This idea was disseminated and traditionalized by institutions of the nation-state: jurisprudence, military forces, political, and administrative bodies. Probably most influential for the creation and dissemination of these fundamental elements of the concept of nation-state were the modern state school systems, which were established simultaneously to the foundation of the nation-state as such. Linguistic homogenization was the main motive for the development of public education systems. The establishment of one national language and of a monolingual national society was (and often still is) seen as essential for the success of the nation-state, especially at the economic level.

In reality, hardly any nation in the world ever had a monolingual population. In most countries – especially in the Australasian, Asian, and African world, but also in Europe – people speak more than one, often many languages (*see* **Bilingualism**). Despite this reality, the deep-seated belief in monolingualism as natural in a society governs individual and public opinions towards language and language practice. In the cases of European nation-states, this preference becomes obvious in connection with immigration. Roughly one-third of the people under the age of 35 years in the member states of the European Unity are migrants, speaking other languages than the national language(s) of the respective state (*see* **Migration and Language**). For example, in the year 2000, more than 350 languages were spoken by children in London schools. Nevertheless, the European state school systems act as if they had monolingual populations. The teaching is centered on the 'legitimate' language of the state or the area, that is to say the national language or the official language of the region. The other languages are rarely taught at schools; children stay illiterate in their second or third language they live in. Consequently, they are unable to develop their other languages towards the most elaborated state (*see* **Bilingual Education**). By these mechanisms, the hierarchy and power relations between languages become stabilized. Those who have no or less access to the legitimate language are at risk of being excluded from participation and equal success in a society.

The linguistic habitus is the governing mechanism of these processes. The notion of linguistic normality was traditionalized in history, despite multilingualism. There is no collective remembrance of these historical events; the fact that this notion once was created and implemented explicitly has disappeared from collective memory. According to Bourdieu's theory, a habitus functions the better, the less conscious its owner is about it.

A variation of the monolingual habitus seems to be at work in multilingual nation-states as well, due to the fact that there is usually one selected language of power. This choice may not be a national language. In colonial or postcolonial situations especially, the language of power very often is not a national language, which by constitution has legitimate status. Instead, it is the language, which guarantees survival and success in the linguistic market – mainly the language of the former colonists. Whereas in Europe, the standard national languages are usually considered the legitimate variant, in colonial situations symbolic power is linked to the languages of the former oppressors (cf. Goke-Pariola, 1993). The linguistic habitus ensures the relative stability of these situations, and thus contributes to the durability of societies of marked disparities in power between different social groups.

No Language Is an Island

All languages borrow lexical and grammatical features from each other, and down through the ages, English has borrowed intensely from a host of other languages, dead (such as Latin and Greek) or alive (e.g., Italian, French, and German). French loanwords now constitute one-third of the lexical inventory of English, a fact that has led to the epithet 'a semi-Romance language' (McArthur, 2002: 135).

Although English today is better known as a linguistic donor than a receiver, English keeps adopting and adapting foreign words, many of which are later re-exported to other speech communities. As a case in point, several exotic late-20th-century food terms, e.g., *taco* and *tortilla* (originally from Spanish) and *sushi* (from Japanese) have reached European kitchens and dictionaries after stopovers in America or Britain. This phenomenon is an obvious parallel to relay translation – as one finds in, for instance, the interpreting services of EU bodies – where language contacts between minor languages are typically mediated by a more dominant language, most often English or French.

In the following section, we will look at some of the mechanics of linguistic influence in general, providing a backdrop for a more elaborate discussion of the English influence on other languages, by far the most conspicuous and wide-ranging type of linguistic influence found today.

Borrowing from Other Languages: Blessing or Curse?

One question that immediately springs to mind when discussing linguistic influence is how such influence comes about. What does it take to export language features, or – viewed from the receiving end – why and how are loans introduced in a language?

In answer to these questions, I will cite two experts in historical linguistics, Lars-Erik Hedlund and Birgitta Hene. In their book *Lånord i svenskan* (Hedlund and Hene, 1992: 70), they establish the following taxonomy of the *raisons d'être* of lexical innovation through borrowing (all terms are translated by me), summarized in **Table 1.**

In contrast to this descriptive and quite complex model, a prescriptive, somewhat simplistic view distinguishes between loans that are needed and loans that are superfluous. As concluded in a pioneering Danish work on Anglicisms (Sørensen, 1973: 131):

Table 1 The reasons behind lexical borrowing

Background	*Motivation*	*Function*
A. Voids in the language	1. Name new phenomenon	Verbalization
	2. Generalize/specify	Verbalization
	3. Express oneself in neutral terms	Information
	4. Express a value statement	Expressiveness
	5. Create certain associations	Persuasion
	6. Add humorous effect	Entertainment
	7. Avoid sounding repetitive	Rhetorical appeal
	8. Obtain a more handy expression	Ease
	9. Express personal or group identity	Psychosocial marker
B. Voids in the sender/receiver	1. Compensate personal lexical voids	Creating a message
	2. Compensate presupposed voids in the audience	Getting the message across
C. Foreign-language original	1. Represent a foreign culture in translation	All above functions

	2. Compensate presupposed voids in the audience	Getting the message across
C. Foreign-language original	1. Represent a foreign culture in translation	All above functions

> As legitimate loans we may accept those words and phrases which serve a sensible purpose, i.e. those that primarily fulfil an informative function. As opposed to this, one should be wary of loans suggested for prestige purposes. [my translation]

However, even superfluous, prestige-driven loans tend to carve semantic niches for themselves (Gottlieb, 2004), and, moreover, it is not easy to judge which motivation(s) may be at play in the borrowing process.

In a recent discussion on German loanwords in English – high-register items such as *Zeitgeist* and *Sprachgefühl* – American-based lexicographer A. J. Meier bridges the need-or-prestige dichotomy with these words:

> The line between need and prestige, however, can be somewhat obscure, given the tendency for foreign words to belong to a more "educated register." Indeed, I would submit that, by virtue of its foreignness, a word attains greater saliency and thus, to some extent, is imbued with greater expressive power, a power concordant with both need and prestige. (Meier, 2000: 169)

As any discussion concerning linguistic borrowing is bound to involve notions of cultural and linguistic power, the debate tends to become emotionally heated. Internationally, the public debate oscillates between the following statements and claims (Table 2).

Still, despite the arguments against borrowing – nowadays typically from English – most speech communities continue doing so with increasing speed; even in self-protective societies such as Iceland, purist measures have a limited effect. Foreign words travel without passports, and as in politics, power is in the hands of laymen, not experts.

The Semantic Functions of Borrowings

Having gained ground, borrowings fall into the following semantic categories:

Table 2 Standard arguments for and against linguistic borrowing

For borrowing	*Against borrowing*
Facilitates learning of donor language	Impedes reading of national classics
Shortens distance between languages and cultures	Increases distance between generations and social groups
Provides expressive enrichment	Leads to linguistic impoverishment
Makes translation simpler	Kills the fascination with foreign languages and cultures
Fights chauvinism and provincialism	Paves the way for foreign cultural dominance

1. Additions. Borrowed expressions refer to new phenomena in the world outside the speech communities adopting them: in many Germanic languages, the Anglicism *AIDS* (or *aids*) came with the disease, so to speak. France managed with a loan translation of the four lexical elements (Acquired Immuno-Deficiency Syndrome), thus coming up with *SIDA*.
2. Replacements. Anglicisms and other-isms often pop up in situations where the entities they refer to already exist in the domestic language: in these years, Danish *sceneskræk* (a direct translation of the English 'stage fright') is gaining ground at the expense of *lampefeber* (from German *Lampenfieber)*. This replacement of a Germanism by an Anglicism is typical of the recent development in minor Germanic speech communities; ironically, in this case the two German components are both found in English ('lamp' + 'fever'), whereas the English-inspired elements *scene* and *skræk* were originally borrowed from French (*scène*) and German (*Schreck*), respectively.
3. Differentiators. Finally, by wedging themselves in, some borrowings may contribute to semantic differentiation: as *rollemodel* (from English 'role model') is now establishing itself in contemporary Danish usage, the existing term *forbillede* (after German *Vorbild*), seems to be acquiring a strictly metaphorical meaning. In other words, part of the semantic range of *forbillede* (that referring to persons) is presently being taken over by *rollemodel*, which can be attested by Danish corpus data. However, a borrowing of this sort, which in the beginning covers only a sub-sense of a domestic word, may one day take over the entire semantic field of that word. In that event, a differentiator turns into (or turns out to be) a replacement. In the case of *rollemodel* in Danish, this is not the case – yet.

Influence from English

For more than a century, English has been immensely successful in influencing languages worldwide. Still, English possesses very few features that fill existing semantic voids in other languages. Naturally, many concepts and products were introduced by English-speaking countries, companies, and individuals. But the fact that, for instance, many Japanese and European brands and product names are English – even names for domestic-market goods – shows that, in certain domains at least, an anglophone ring adds to the value of things.

The English influence is generated by three interconnected factors:

1. Most opinion leaders worldwide are dependent on English as a second language, both for personal communication and for information gathering, and even children in a number of officially non-English-speaking countries rely heavily on their command of English when surfing the Internet, listening to rap and rock songs, and watching TV series and films (whether subtitled or not).
2. English is unrivaled as a cover-all language: it is usually the first language in which new technology, trends, and lifestyles are presented internationally, and a language increasingly used worldwide as a lingua franca, even when no native speakers of English are present. In virtually every country on the planet, English is now the first foreign language taught in school. Within the last two decades, Russian, French, Spanish, and German have all lost the status of primary foreign language outside the nations and regions in which they are officially spoken.
3. An increasing part of the media input in the modern world consists of texts translated or in some other way derived from English sources. In great parts of the world, most films, TV series, computer games and novels are anglophone imports, all of this having a major impact on the national languages (Gottlieb, 1999, 2001).

National and regional languages are not just influenced by English, but in academic and business communication, they have *de facto* lost several domains. Today, in a number of countries, the credo 'certain things are best expressed in English' not only is heard among blasé cosmopolitans, but also is often uttered by government officials and businessmen, even by school children.

The Notion of Anglicism: Establishing a New Paradigm

In the various national debates concerning contemporary English-language influence, emotions often replace empirical facts, as ill-defined concepts are used for polemical effect. Below I will suggest a neutral terminology, including a typology to embrace all types of linguistic influence, with English as the influential language, and with Anglicism as a key concept. However, before defining this term, two related key concepts will be addressed:

1. English. In today's language-political discussions, 'English' rarely refers to England, not even to Britain. The central reference here is, not surprisingly, the United States. In most speech communities, 'influence from English' means (linguistic) influence from the United States, the dominant anglophone nation. Since the breakthrough of sound film in Hollywood in the late 1920s, Britain has played second fiddle in the spread of Anglo-Saxon values and linguistic features, although in most European countries most teachers of English still try to emulate a British, i.e., RP, accent in their daily work.
2. Loan words. First, thousands of Anglicisms are not direct loanwords, but belong to one of the many other categories of Anglicism (see the typology below). Second – as goes for all borrowings – Anglicisms are not loans to be paid or handed back to the donor language at a later stage. Instead, they can be seen as either 'stolen goods' or rather as the fertile offspring of other speech communities' planting of English seeds. The foreign soil is also the reason why, quite often, when working into English, the best translation of an Anglicism is not the same expression in English.

Traditionally, scholars have defined an Anglicism as "a word borrowed from the English language which is adapted with respect to the linguistic system of the receptor language and integrated into it" (Sicherl, 1999: 12). This definition should be praised for emphasizing that, once borrowed, loans – if they manage to survive – may remain forever with the borrowing language and may in that process change pronunciation, spelling, meaning, etc.

However, two serious objections to this type of definition can be raised:

1. It is too narrow. It only looks at the most conspicuous elements of language: the individual lexical items. Morphological, syntactic, and other features are ignored.
2. It expresses a naive integrational paradigm, which is no longer generally valid, that of stable domestic language structures which eventually digest and integrate all (English) loans. What happens between English and other languages today points to a paradigm of systemic influence. In an increasing number of speech communities, especially Germanic ones, English linguistic features – even grammatical ones – are now adopted, rather than adapted. And even in exotic speech communities under the spell of English, the common practice of code-shifting overrules potential gaps in language systems that would prevent direct transfer of English language features and norms.

What is, then, a reasonable definition of Anglicism? In order to cover the entire spectrum of present-day influence from English, the notion of Anglicism should be defined as 'any individual or

systemic language feature adapted or adopted from English, or inspired or boosted by English models, used in intralingual communication in a language other than English.'

Based on this definition, the taxonomy in Tables 4–6 encompasses all linguistic phenomena caused by English influence. As illustrated in Table 3, the taxonomy rests on a two-by-two categorization based on two distinctive features:

1. The distinction found in the Anglicism definition above, between, on the one hand, items that are either adopted (i.e., retained, and thus obviously of English heritage) or adapted (i.e., camouflaged or literally translated into the recipient language) and items that are inspired or numerically boosted by English language phenomena.
2. The distinction between microlanguage items (including morphemes, phonemes, lexemes, phraseology, and syntax), and macrolanguage ones (phenomena found at clause, sentence, or text level).

The reason why my categorization has yielded a tripartite taxonomy – and not four main categories – is the following: I have not included reactive macrolanguage Anglicisms, a potential category that is almost impossible to operationalize, as it is hard to determine whether a given sentence or text (type) is inspired by English or not.

In Tables 4, 5, and 6, each subcategory is exemplified, and the English trigger behind each example is given, something that is especially needed when dealing with reactive Anglicisms, which by definition hide their English ancestry to native speakers and foreign observers alike.

Some of the terms used in the taxonomy are well established and universally agreed upon – e.g., semantic loans and morphosyntactic calques – while others are new (sentence-internal vs. sentence-shaped shifts, for instance). Finally, there are terms that are debated, yet too established to deserve being discarded altogether: 'borrowing' and 'loan' are thus preferred to the neologism 'import word,' although this term reflects the true nature of linguistic influence.

Table 3 Key parameters in categorizing Anglicisms

	Subclause items	*Clause, sentence, and text items*
Adapted or adopted from English	Active Anglicisms	Code-shifts
Inspired or boosted by English models	Reactive Anglicisms	[not included in present model]

Anglicisms and Acceptability

In addition to the structural classification presented in Tables 4, 5 and 6, a language–political categorization can be applied to Anglicisms, as not all of them reach acceptance by (all) language users in the affected speech community. At any given time, depending on a number of factors – the type of Anglicism, a particular item's (lack of) prestige, its usage history, etc. – individual items can be ranked as follows, in decreasing order of acceptability:

1. Integrated items (not intuitively identified as English loans, accepted by all): French *flanelle* < English *flannel*, probably from Welsh *gwlanen*
2. Naturalized items (identified as English loans and commonly accepted): Romanian *interviu* < English *interview;* Hungarian *marketing* (= English)

Table 4 Active Anglicisms

Category	*Type*	*Examples*	*English trigger*
Overt lexical borrowings	Single-word unit	*branding* (Danish)	'branding'
	Multi-word unit	*Learning by Doing* (German)	'learning by doing'
	Sub-word unit	*-minded* (Norwegian)	'-minded'
Covert lexical borrowings	Single-word unit	*keks* (Slovene)	'cakes'
	Multi-word unit	*Stop en halv!* (Danish) [literally 'stop one half']	'Stop and haul!'
Loan translations	Compound substitute	*involtino primavera* (Italian)	'spring roll'
	Multi-word substitute	*tað er at siga* (Faroese)	'that is to say'
Hybrids	Partial loan translation	*Computerkunst* (German)	'computer art'
Pseudoanglicisms	Archaism	*butterfly* (Danish)	'butterfly tie' (= bow tie)
	Semantic change	*overhead* (Norwegian) (= slide, OHP transparency)	'overhead'
	Contamination	*after-ski* (Swedish)	'after' + 'ski' (English: 'apres-ski')
	Morphological change	*fit for fight* (Swedish)	'fighting fit'
	Jocular derivation	*webmoster* (Danish) [literally 'web auntie']	'webmaster'

3. Implants (English-sounding, accepted by certain user groups only): Finnish *benchmarking* (= English); Danish *hænge ud* < English *hang out*
4. Interfering items (often inaccurate solutions, including mistranslations): (Danish *militære barakker* < *(military) barracks*; correct term: *kaserne*, originally from French *caserne* via German *Kaserne*).

Extending the natural metaphors used in the four terms above, one could say that these four categories represent not only a cline in terms of acceptability, but also a Darwinist race for survival, with many Anglicisms beginning their life as interfering items, which – as in the above example – may mislead the unsuspecting reader: in Danish, *barakker* are poorly built one-story houses. Some new, interfering Anglicisms, which in written sources are often printed in quotation marks or italics, reach the implant stage, and out of these only a few become naturalized, or end up as fully integrated items.

With respect to idiomaticity, the watershed goes between types 2 and 3 above. To most language users, items of types 3 and 4 are seen as foreign or unwanted.

When Linguistic Influence Leads to Language Death

It is not the intention here to warn against foreign-language influence, a primary source of renewal and growth of any language, including English. On the other hand, as with drugs and other substances, what is found stimulating in small doses may kill in large quantities, and language death is indeed an issue here. In northern Europe, English has all but wiped out several Gaelic languages – with Welsh presently fighting its way back from near-extinction – and it certainly has exterminated the Norse language spoken in the Orkneys until a few hundred years ago.

Today, more than military invasions or political power, the media are instrumental factors behind the

Table 5 Reactive Anglicisms

Category	*Type*	*Anglicism*	*Standard*	*Trigger*
Semantic loans	Extensions	*lernen* (German)	*wissen* (= know)	'learn'
	Reversions	*overhøre* (Danish)	*høre* (= hear) [overhøre = ignore]	'overhear'
	Limitations	*morgen* (Danish)	*nat* (0–5 A.M.) *morgen* (5–9 A.M.) *formiddag* (9–12 A.M.)	'morning'
Orthographic loans	Changed spelling	*literatur* (Danish)	*litteratur*	'literature'
	Changed punctuation	*Den erfarne amerikanske senator, Joseph Biden, har en anden udlægning.* (Danish)	*Den erfarne amerikanske senator Joseph Biden har en anden udlægning.*	'. . . American senator, Joseph Biden, has . . .'
Phonetic loans	Phonetic changes	*unik* pronounced as [you'nik] (Danish)	[oo'nik]	'unique'
	Prosodic changes	falling intonation in exclamations (Brazilian Portuguese)	slightly rising intonation	Standard American intonational pattern
Morphosyntactic calques	Inflections	autobahn*s* (Danish)	plural *–er*	-s
	Phraseology	*Hier sind Sie.* (German)	*Bitte sehr.*	'Here you are.'
	Constructions	Es *un* maestro de escuela (Spanish)	Es maestro de escuela	'He's **a** teacher'
	Word order	*Dog, han vil ikke* . . . (Danish)	*Han vil dog ikke* . . .	'However, he will not . . .'
	Valency	*Ring en ekspert* (Danish)	*Ring til en ekspert / Tilkald en ekspert*	'Call an expert'
	Prepositional choices	*ud af vandet* (Danish)	*op af vandet* [op = up]	'out of the water'
Translationese	Favorized cognates	*còpia* (Catalan) [. . . of a book]	*exemplar*	'copy'
	Default equivalents	*anlända* (Swedish)	*komma*	'arrive'

continuing triumphs of English on the world map. And as people add English to their personal repertoire of languages, Anglicisms are adapted and adopted into their local vernaculars, whether spoken by hundreds of millions, as Chinese or Portuguese, or only by hundreds of thousands, as Icelandic and Faroese. Whether local languages lose domains in the process or even end up losing all their speakers is decided by their users, not by native speakers of English or anglophone institutions.

Taking Denmark as a typical example of a speech community under English influence, the most important agents in the ongoing anglification are the national media, especially those whose texts are based on anglophone sources. Responding to a seminal Danish study on the impact of English (summarized in Preisler, 2003) – in which influence from above, i.e., the educational system and the business world, is amplified by influence from below, e.g., U.S.-inspired youth subcultures – the doyen of Danish Anglicism research, Knud Sørensen, points out that in his view "the most important impact of English might be termed *influence from the middle,* i.e. the influence exerted by the press" (Sørensen, 2003: 354).

Ironically, a large part of the media-generated Anglicisms are not deliberately created for effect; strict deadlines simply do not go well with idiomaticity when you are juggling with two languages. In Sørensen's terms, "a journalist who works with an English-language source at his elbow will often be tempted to take the line of least resistance and make a rough translation of an English idiom, sometimes forgetting whether it will make sense to his Danish readers" (Sørensen, 2003: 349).

With an all-pervasive issue such as the English influence on cognate languages, we easily find ourselves in a chicken-and-egg situation. Whether we argue that the media merely reflect the linguistic realities of youthful customers and audiences – the position taken by Preisler – or that the media play a more proactive role in the continuing anglification of other languages – Sørensen's point – does not make much difference. The fact remains that the English influence comes from everywhere, is felt by everyone, and has effects everywhere in the given domestic language, with Danish as a case in point.

As Danish dialects are dying out – at a rate still matched by few other European languages – we may soon advance to a situation where Danish itself becomes a dialect, shared by future bilinguals from the Danish Isles. Just like Danish speakers of the Southern Jutland dialect *sønderjysk* used to switch off Standard Danish when meeting old friends in urban Denmark, Danes reading English paperbacks, watching American films and using English at work may in the future switch off English when they spend time with family and friends, in what may be the only domain of Danish not yielding to English: the intimate sphere. Today, Danes who master English – and who accept a modicum of English influence on Danish – are comparable to those who, 100 hundred years ago, were ahead of their peers in adopting Standard Danish as a prestigious alternative to their traditional dialects, now nearly extinct (Hjarvard, 2004).

Table 6 Code-shifts

Category	*Example*	*Pragmatic context*
Tags	, *okay?*	Standard oral interpersonal assurance formula
Sentence-internal shifts	. . . *en person som under press kan* 'blow the cover sky high!'	Lines from a (Norwegian) novel
Bilingual wordplay	'De Frygtløse' – *'The Muuhvie'* (Danish title for the American animated movie [featuring cows] 'Home on the Range,' 2004)	Common linguistic device in commercial punchlines and political slogans in semibilingual speech communities
Sentence-shaped shifts	*Way to go, girl!*	The final words in a (Danish) music review
Total shifts	'*Visit the World's Biggest LEGO Shop*' (Website for Danish toy company only in English)	Addressing locals and foreigners through English-only communication.
Domain losses	*'Layout construction: a case study in algorithm engineering'*	Title of an academic research paper written by four (Danish) scientists. (In some countries up to 90% domain losses in computer games, scientific papers, pop lyrics, and certain business documents; more moderate losses in domains such as advertisements, commercial brands and film titles.)

Metaphors We Drown By: Forever Flooded by Anglicisms?

The debate on Anglicisms is international and goes back more than 100 hundred years to the days when millions of Europeans fled their countries hoping for a better future in English-speaking North America and Australia. This wave of poor emigrants coincided with the heyday of the British Empire around the turn of the 20th century. And that was the time when the first critical voices were raised in the apparently never-ending debate on English linguistic influence abroad. Especially in Germany, the impact was strongly felt at an early stage (Dunger, 1899). Even the flood metaphor, portraying the exposed language as a victim of some natural disaster, seems to be a veteran term: referring to the period before 1914, a later observer noted that "the flooding of German life and the German language with English had reached such an extent that the whole situation for Germany appeared almost threatening" (Stiven, 1936: 101, cited in Viereck, 1986: 110).

Also in France, a country renowned for its linguistic conservatism, oceanic terms have been used for what happened to the national vernacular in the late 20th century. According to one German linguist:

> Purism has sterilized the language. The French are desperately afraid of coining new words. This linguistic Malthusianism is ultimately responsible for the fact that thousands of foreign words flood into the gap which has to be filled somehow. (Hausmann, 1986: 87).

This textbook case of German *Schadenfreude* demonstrates that in a modern world, what seemed to be difficult already before WW1 is now impossible: English cannot be kept back. Instead, bilingualism could be the answer, paired with an increased awareness of everything that pertains to (one's own) language and culture.

Still, waves are always washed away by other waves, and "many loans seem to be part of trends and waves that make a lot of noise, but are relatively soon forgotten" (Graedler, 2002: 79). What is crucial here, however, is that these recurrent phenomena – short-lived or not – are always English; neither Europe's most spoken mother tongues (Russian and German) nor the only billion+ language worldwide (Mandarin Chinese) seem likely to compete with English in this respect.

When it comes to successful export of linguistic features, the only near-future rival to English may be Arabic, representing an Islamic culture that is now the only vocal challenge to Anglo-Saxon globalization, and thus a language with an enormous potential for covert prestige in the eyes of non-anglophone subcultural and linguistically trend-setting groups the world over. So far, apart from a few 'tasty' words such as *kebab* and *shawarma,* recent European loans from Arabic tend to represent notions related to religion and politics, words that often acquire sinister connotations in the process: *fatwa, ayatollah, mullah, imam, sharia, ramadan, intifada, sunna, burka*, and *jihad*.

The Development of Anglicisms

As we have seen, influence from English may take many forms and create many different types of linguistic offspring. An example of how differently English loans may develop over time is found in Hong Kong Chinese and Japanese, respectively (Chan and Kwok, 1986; Ishiwata, 1986). In Chinese as spoken in Hong Kong, the situation prior to the integration of the ex-English crown colony was typically as follows:

> Some loanwords may enjoy a brief popularity and are gradually replaced by terms which are more meaningful. [...] Take the example of 'laser'. It entered the Chinese lexicon as [lœy se]; today it is being replaced by the descriptive [gik gwoŋ] or 'piercing ray' (Chan and Kwok, 1986: 415).

Expressed in structural terms, what happens with the 'laser' type Anglicisms in Hong Kong Chinese is that what was launched as an incomprehensible phonetic loan (an overt lexical borrowing) ended up as an all-Chinese neologism, immediately comprehensible to the speaker. Of course, this is not a unique Asian phenomenon; in several languages, not only loan translations offer themselves as successors to pioneering English-sounding terms: quite often the original Anglicisms yield to expressions that cannot by any standards be termed Anglicisms.

In Japan, the opposite tendency seems to have been at work for more than a century. Whereas prior to the Meiji restoration in 1869, Japanese coined its own translations of (scientific) terms of English origin, "it has become more and more common to adopt the western terms as they are without any attempt at translation" (Ishiwata, 1986: 459).

As indicated earlier, this is exactly the situation in several European speech communities today. While, for instance 50 years ago, in German the Greco-English compound 'television' became *Fernsehen*, decades later 'telefax' was taken over as *Telefax*. Along the same lines, in Denmark cinema 'thrillers' were baptized *gysere* (a literal translation of the term) as this genre was introduced to Danish cinema audiences in the early 1930s, but today's Danish DVD

patrons exclusively use the term 'thriller'. In the passing years, the word 'gyser' has increasingly been used metaphorically: in recent press reportage, the term typically refers to sporting events, political elections, and the like. This wedging in of a new term (ironically, in this case, the original English term) allows the existing word to take on a new meaning, or at least new connotations. If the old term is not lost in the process, we have a case of language enrichment.

Dictionaries on –isms: Testimonies of Linguistic Influence

Given the historical and present importance of borrowings, a vast number of general foreign-word dictionaries have been compiled. Yet dictionaries attesting the influence of languages such as French, German, and Russian are sorely missing, and largely nonexistent, a fact that is lamented by one of Europe's leading names in contact linguistics in his chapter entitled 'Wanted? Dictionaries of Gallicisms, Germanisms and neo-classic diction' (Görlach, 2003: 124–162). Anglicism dictionaries, however, seem to flourish, as documented in a comprehensive bibliography comprising dictionaries and other publications on Anglicisms (Görlach, ed., 2002). Still, as long as national lexicographical definitions and resources vary considerably, one cannot conclude from dictionary data on Anglicisms to linguistic realities concerning their relative numbers – nor their frequencies – in a given set of languages, as shown in a study comparing Anglicism dictionaries from four Germanic speech communities (Gottlieb, 2002).

The Introduction of Anglicisms

Anglicisms may be introduced through either personal or impersonal contacts between an anglophone source and a non-anglophone target.

Personal Contacts

The first wave of Anglicisms in the speech communities surrounding Britain was found in the 18th century. Mediated by sailors, English nautical terms were introduced overseas. Today, most of these loans are integrated in the borrowing languages, and in Denmark nobody except etymologists realizes that words such as *kutter* (fishing vessel) and *splejse*, meaning 'sharing expenses between friends' (from 'splicing' ropes) are English loanwords. When this influence from below was first felt outside Britain, the ruling classes abroad began mediating English influence from above in adopting English terms and habits, including everything from *gentleman* and *gin* to *tennis* and *golf*.

Outside Europe, colonial elites picked up English, and since then the English influence has been felt in national and local languages throughout what is now termed the Commonwealth nations. In similar fashion, non-English-speaking countries in the American hemisphere – the Philippines, for instance – were heavily influenced by American English long before the Second World War.

Even today, in most of the world's non-anglophone speech communities, personal contacts constitute an important channel through which English language features are introduced. A poignant example is found in the influential foreign-based reporters often operating in English even when based in an area where English is not the national language, e.g., the Middle East.

Yet since the 1940s at least, most Anglicisms result from impersonal contacts. They are introduced in target languages – directly or via intermediary languages – through literature and the mass media, as discussed in the following sections.

Impersonal Contacts

Today the media play a more decisive role in language change than do personal contacts; the latter nowadays tend to stimulate foreign-language skills rather than influence the native tongues of those involved.

Original Products: Direct English Input A major dividing line within the impersonal contacts category runs between translated and original (or nontranslated) entities. Most of the original products are nonverbal, though as symbols of Anglo-American lifestyle, they have a major impact on the language in the cultures in question. Original nonverbal products include clothes, food, media technology, etc. Among the verbal products presently consumed untranslated in non-anglophone speech communities, not least by the young, are rock songs, video games, printed fiction, CNN-type news coverage, and Internet communication in English, phenomena contributing to the possible future loss of domains for the domestic languages.

Translated Products: Anglicisms Every Minute This subcategory covers books, technical documentation, films, DVDs, and TV programs, often comprising a major part of the total consumption in non-anglophone countries. In Denmark, some 40% of what people read – TV subtitles included – is translated from English (Gottlieb, 1997: 148–153).

All over the world, the audiovisual, or polysemiotic, media – television, video, DVD, and film – are instrumental in introducing language change. The

first study to focus on Anglicisms on the screen (Sajavaara, 1991) highlighted the role of TV subtitles in the ongoing English influence on Finnish, a language which does not belong to the Indo-European language family.

In Spain, one of Europe's major dubbing countries, critical observers have long talked about "the effect that English is having on the Spanish speaker at home as a result of the vast quantities of badly translated material flooding the spheres of journalism, radio, television, and advertising" (Lorenzo, 1996: 18, quoting A. Gooch: *Spanish and the onslaught of the Anglicism*).

A phenomenon often mentioned in this context are the all-pervading morphosyntactic calques (cf. Table 5). Certain types of calque are more representative of dubbing, in which the translated lines should fit the rhythm of the original dialogue, often leading to unidiomatic and English-sounding versions (Herbst, 1994 on German dubbing, Gottlieb, 2001 on dubbing in Denmark). Other types have become almost second-nature to subtitling from English, in which viewers hear – and very often understand – the actors' original lines. An often-cited example of this is the transfer of the English 'question plus affirmative answer' sequence in dialogue situations where many other languages use the opposite pattern to express the same verbal exchange. In subtitling, the idea of viewers hearing a *yes*, but reading a *nej* ('no') seems to terrify most translators.

Even in dubbing countries, the transfer of such questions-cum-answers seems to be a problem. In order to avoid Anglicisms, the Catalan Televisío de Catalunya dubbing stylebook (1997: 62) urges translators to render the lines

– Because you didn't want to be a witness, right?
– Yes.

as

– Perquè vostè no volia fer di testimoni, oi?
– No.

As in subtitling, the idiomatic solution often sounds wrong, by English standards, which may prevail if morphosyntactic calques continue to appear as frequently as now.

That such calques and other reactive Anglicisms are indeed common in contemporary (film and TV) translations, both in dubbed and in subtitled versions, is documented in a study (Gottlieb, 1999) looking at unintegrated and unidiomatic Anglicisms in the subtitles of two American films broadcast by Danish public-service TV. These two films contained an average of 0.43 and 0.57 unassimilated Anglicism tokens per minute, respectively.

In a follow-up study comparing the dubbed and subtitled video versions of three American family films (Gottlieb, 2001), the subtitled versions displayed Anglicism densities of 0.50, 0.57, and 0.73 tokens per minute, while the dubbed versions contained more than twice as many Anglicisms: 1.04, 1.77, and 1.85 tokens per minute, respectively. In conclusion, both screen translation methods seem to play a very active role in the anglification of the target languages involved.

Within the realm of books and other monosemiotic media, there is a scarcity of empirical work comparing Anglicisms in translations and original texts. However, a major Swedish study comparing the vocabulary in 27 novels translated from English with 29 native Swedish novels found a general tendency toward translationese, with many default equivalents (cf. Table 5), thus confirming common knowledge among translation scholars and critics: "Many English words seem to trigger a standard translation in Swedish although the Swedish translation differs stylistically from the English original." (Gellerstam, 1986: 91).

Anglification Beyond Words

Not only translated texts – which make up a significant part of present-day mass communication in any minor speech community – reveal that non-anglophone language systems are currently being anglified. Also original discourse may tell of English influence, as the personae we create in fiction and the world view we express in nonfictional genres often emulate British and American models. In several speech communities, lexis, phraseology, semantics, syntax, and morphology are in a state of flux; some established domestic words resembling their English synonyms obtain boosted frequencies (cf. the favorized cognates subcategory in Table 5), and even the phonemic system is undergoing changes, with English phonemes getting a foothold in standard pronunciation.

In quantitative terms, Anglicisms may not seem so conspicuous in European languages today. Yet a considerable part of the present growth and development of Western languages is triggered by English. In Danish, for instance, the vocabulary is being reshuffled, and not only are more than half of all new words inspired by English (Gottlieb, 2004: 49), but these loans – typically nouns – tend to carry significant semantic weight: "Those are the words that are instrumental in creating our world view, [...] and this means that to an increasing extent we let another culture with its language govern our reality" (Jarvad, 1995: 135; my translation).

In the same vein, Finnish linguist Paavo Pulkkinen notices that since World War II, the number of new

semantic loans in Finnish has increased at a higher rate than the number of loan translations. He suggests that the reason for this shift (from active to reactive Anglicisms) is that "numerous Finns have recently begun thinking partly along Anglo-American lines" (Pulkkinen, 1989: 92; my translation).

Clearly, the notion of Anglicism has major implications nationally as well as internationally. With English as a modern lingua franca, the more cross-national communication, the more Anglicisms in the world's languages, the more easily people will understand each other.

In turn, this may imply that real English is changed in the process. Especially in Europe, non-native speakers of English sometimes understand each other better if their English contains shared un-English syntactic or semantic features transferred from their individual languages. Imagine for instance a Frenchman and a German successfully using the word 'eventually' in the same non-native way. Even outside Europe, such shortcuts may make sense: in Japanese, the word *barakku* means the same as the Danish *barak,* as opposed to the meaning of *barracks* in English.

However, the danger remains that the world is reconceptualized in Anglo-American terms. But again, in a politically and economically lopsided world – with anglophone cultures setting the agenda more than ever – getting rid of Anglicisms in defense of linguistic purity would only be possible with draconian measures. Paradoxically, in modern society the steady anglification of domestic languages may prove to be a litmus test of their viability. Although loss of domains is an immanent risk to national languages, in our day and age, a pure language is a fossilized one.

Linguistic Paradigms

T W Stewart, Truman State University, Kirksville, MO, USA

© 2006 Elsevier Ltd. All rights reserved.

The word *paradigm* has garnered much attention since Kuhn's (1962) influential treatment of scientific revolution with respect to paradigm shifts. 'Paradigm' there refers to a broad frame of reference for scientific conceptualization and investigation, following from a set of shared assumptions about what the world is like. In the linguistic context, however, 'paradigm' is primarily used as a morphological term that refers to an organized space of potential words or word-forms related to a common base element.

The most commonly encountered instance of the linguistic paradigm is a systematically collected array of inflectionally related word-forms. Such an array is laid out in the form of a table (see **Table 1**), and columns and rows within the table are defined by contrasting values of inflectional features (*see* **Design Features of Language**).

There is a long-standing tradition of presentation of word-forms in paradigms in both descriptive and teaching grammars, where systematic elicitation or presentation guides the design of visual representation. It is not the case, however, that all approaches to morphological description agree on the adequacy of the notion of paradigm for theory construction.

Linguistic morphological theory can proceed from one fundamental assumption about the basic units of the lexicon. The decision whether to adopt a morpheme-based or a lexeme-based conceptualization of morphology's most relevant level of description determines the relevance (or irrelevance) of the paradigm as a descriptive tool.

In a morpheme-based theory of morphology, the grammar describes the assembly of complex morphological objects out of minimal meaningful forms, i.e., morphemes. In a morpheme-based theory, inflected word-forms are not integrally related to one another; they simply contain a greater or lesser number of morphemes in common. The paradigm, therefore, is a merely descriptive conceit – it is epiphenomenal, and not part of the grammar proper. For this reason, morpheme-based theories make no special prediction about the relative relatedness of inflected words containing the same lexical stem versus those containing the same inflectional affix.

In a lexeme-based theory, by contrast, the lexicon is organized according to abstract word-like units, or lexemes, and inflectionally related word-forms are related in the lexicon via their dependence on a unique lexeme. In a lexeme-based theory, therefore,

Table 1 Paradigm of the Latin adjective *bonus* 'good'

Linguistic Paradigms

T W Stewart, Truman State University, Kirksville, MO, USA

© 2006 Elsevier Ltd. All rights reserved.

The word *paradigm* has garnered much attention since Kuhn's (1962) influential treatment of scientific revolution with respect to paradigm shifts. 'Paradigm' there refers to a broad frame of reference for scientific conceptualization and investigation, following from a set of shared assumptions about what the world is like. In the linguistic context, however, 'paradigm' is primarily used as a morphological term that refers to an organized space of potential words or word-forms related to a common base element.

The most commonly encountered instance of the linguistic paradigm is a systematically collected array of inflectionally related word-forms. Such an array is laid out in the form of a table (see Table 1), and columns and rows within the table are defined by contrasting values of inflectional features (*see* **Design Features of Language**).

There is a long-standing tradition of presentation of word-forms in paradigms in both descriptive and teaching grammars, where systematic elicitation or presentation guides the design of visual representation. It is not the case, however, that all approaches to morphological description agree on the adequacy of the notion of paradigm for theory construction.

Linguistic morphological theory can proceed from one fundamental assumption about the basic units of the lexicon. The decision whether to adopt a morpheme-based or a lexeme-based conceptualization of morphology's most relevant level of description determines the relevance (or irrelevance) of the paradigm as a descriptive tool.

In a morpheme-based theory of morphology, the grammar describes the assembly of complex morphological objects out of minimal meaningful forms, i.e., morphemes. In a morpheme-based theory, inflected word-forms are not integrally related to one another; they simply contain a greater or lesser number of morphemes in common. The paradigm, therefore, is a merely descriptive conceit – it is epiphenomenal, and not part of the grammar proper. For this reason, morpheme-based theories make no special prediction about the relative relatedness of inflected words containing the same lexical stem versus those containing the same inflectional affix.

In a lexeme-based theory, by contrast, the lexicon is organized according to abstract word-like units, or lexemes, and inflectionally related word-forms are related in the lexicon via their dependence on a unique lexeme. In a lexeme-based theory, therefore,

Table 1 Paradigm of the Latin adjective *bonus* 'good'

	Masculine		*Feminine*		*Neuter*	
	Singular	*Plural*	*Singular*	*Plural*	*Singular*	*Plural*
Nominative	*bonus*	*bonī*	*bona*	*bonae*	*bonum*	*bona*
Genitive	*bonī*	*bonōrum*	*bonae*	*bonārum*	*bonī*	*bonōrum*
Dative	*bonō*	*bonīs*	*bonae*	*bonīs*	*bonō*	*bonīs*
Accusative	*bonum*	*bonōs*	*bonam*	*bonās*	*bonum*	*bona*
Ablative	*bonō*	*bonīs*	*bonā*	*bonīs*	*bonō*	*bonīs*

The paradigm is defined with respect to the inflectional features 'Gender,' 'Number,' and 'Case.'

the paradigm is not merely convenient for description; it is an organizing principle of the inflectional component of grammar, and the cells of the paradigm contain forms that instantiate the lexeme as suitably modified morphologically for use in particular grammatical contexts. The prediction may follow from this that the inflectional forms of a single lexeme are related in a special way, and this may be borne out in, for example, reaction times in a psycholinguistic priming task.

The traditional typological characterization of languages as isolating, fusional, or agglutinating (a division that is both descriptively nonexhaustive and an oversimplification for almost any given individual language) may bear on the apparent utility of the paradigm on even a descriptive level. For example, a highly agglutinating language, such as Turkish, has very few co-occurrence restrictions on inflectional morphology, and so it has a paradigm that is potentially quite complex (see Table 2).

On the other hand, a highly isolating language such as (Mandarin) Chinese makes most of its grammatical contrasts by introducing discrete function words (adpositions, auxiliaries, etc.,) and distinct syntactic constructions. In other words, there is little inflectional morphology in Mandarin, and so there is little motivation for an abstract lexeme separate from the surface word, and the notion of the paradigm is therefore rendered otiose.

Since isolating languages have no inflectional morphological paradigms to speak of, the question may arise as to the possibility of morphological analogy in such languages, that is, of so-called 'paradigm-leveling,' in which synchronically irregular forms are remade on analogy with inflectionally related, regular word-forms. Proponents of the Lexical Diffusion school of language change, many of whom work principally with Chinese data, dismiss out of hand the possibility of analogical influence in cases of irregular change. Analogy as a linguistic strategy has never been limited to inflectional paradigms, so although it is a fair step to set aside considerations of paradigm leveling in Chinese, it does not necessarily follow that analogy is not applicable in Chinese linguistic change.

The paradigm thus seems most useful for the presentation of languages with considerable inflectional morphology, but at the same time, with limits on the number of features that may be realized on any given word-form. This best describes fusional languages, and it is perhaps not surprising that the paradigm is especially common in the history of linguistic description of Indo-European languages, many of which can be characterized as fusional, or else minimally agglutinative.

The above descriptive difficulties associated with Turkish and Mandarin point to two further theoretical issues:

1. Do speakers store full paradigms of word-forms in their heads and select words from this set, no matter how many forms this entails (cf. Odden, 1981 on the potential for literally trillions of grammatically distinct verb forms for each and every Shona verb), or do the contrastive features define the paradigm space, and general morphological rules allow for the computation of inflected word-forms?
2. Is the only sensible use of the paradigm to be found in a traditional morphology with the word-form as the upper limit? Might one rather extend 'grammatically related' into the realm of collocations of content and function words, i.e., periphrastic expressions?

Both of these questions are open and active in linguistic research, although the traditional conceptualization of morphology (as the formation of words and the study of their constituent parts and/or relationships) has militated against multiword units within paradigms.

It is only in the context of a paradigm that one may refer to a *defective paradigm*, i.e., the situation in which a lexeme lacks a particular inflected

Table 2 A fragment of the morphological paradigm for Turkish *deniz* 'ocean'

	'X'	*'to X'*	*'of X'*	*'in X'*	*'from X'*
Singular	deniz	denize	denizin	denizde	denizden
Plural	denizler	denizlere	denizlerin	denizlerde	denizlerden
Diminutive sg.	denizcik	denizcike	denizcikin	denizcikde	denizcikden
Diminutive pl.	denizcikler	denizciklere	denizciklerin	denizciklerde	denizciklerden
'my X'	denizim	denizime	denizimin	denizimde	denizimden
'your (sg.) X'	denizin	denizine	denizinin	denizinde	denizinden
'our X'	denizimiz	denizimize	denizimizin	denizimizde	denizimizden
'your (pl.) X'	deniziniz	denizinize	denizinizin	denizinizde	denizinizden
'my Xs (pl.)'	denizlerim	denizlerime	denizlerimin	denizlerimde	denizlerimden
'our Xs (pl.)'	denizlerimiz	denizlerimize	denizlerimizin	denizlerimizde	denizlerimizden

word-form when it would be expected, all else being equal, to possess such a word-form. In English, an example is in the paradigm of the verb STRIVE, which for most speakers lacks a past/passive participle, or at least there is a significant lack of consensus on what it should be: ?*striven*, ?*strove*, ?*strived*. Any of these may be generated by a more or less productive rule of English verb morphology (cf. DRIVE vs. DIVE vs. THRIVE), and as such, the hesitation to choose a form with certainty indicates a (perhaps accidental) gap in the paradigm. A full discussion of gaps is beyond the scope of this article, but it should be pointed out that whole classes of lexemes may lack a particular form or set of forms for semantic or pragmatic reasons or for reasons of pure historical accident. In either case, the result is a paradigm that may be seen as defective with respect to the inflectional paradigms of other, comparable lexemes in the language in question.

As a final consideration, there may be in some cases a motivation for the addition of derivationally related words to the discussion of paradigms. That is, one may speak of regular derivation as operating within the space of a derivational paradigm, with different base words and their derivatives standing in comparable relations to their counterparts in other derivational paradigms. For example, *sing* > *song* > *singer* is analogous to *shoot* > *shot* > *shooter* within an abstract paradigm {Action} > {Result} > {Agent}. Discussion of derivation in paradigmatic terms is somewhat problematic, given that each lexeme in turn licenses an inflectional paradigm of its own. Although there exists considerable discussion of a formal compartmentalization of derivation and inflection (the so-called 'split-morphology hypothesis'), there are numerous languages in which a strict sequencing of inflectional markings outside of derivational ones is not respected. In such cases, therefore, paradigmatic intermingling may be more clearly motivated.

Linguistic Reality

L Wetzel, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Linguistic reality is that portion or aspect of reality that linguistics seeks to understand and explain, and in virtue of which true linguistic claims are true. Linguistics is the scientific study of language, its units, nature, and structure. To see what the units, nature, and structure of language are, we should look to what linguists say. A reasonable place to begin is *An encyclopedia of language*. It reveals that in addition to languages and language users, phonetics cuts up linguistic reality into vowels, consonants, syllables, words, and sound segments, the human vocal tract and its parts (the tongue has five), among other things (*see* **Phonetic Pedagogy**). Phonology is also concerned with sounds, but organizes them in terms of phonemes, allophones, alternations, utterances, phonological representations, underlying forms, syllables, words, stress-groups, feet, and tone groups (*see* **Phonology: Overview**). In grammar, morphology describes morphemes, roots, affixes, and so forth, and syntax analyzes sentences, semantic representations, LF representations, among other things (*see* **Grammar**). Semantics studies signs, their meanings, their sense relations, propositions, etc. Pragmatics deals with speech acts, speaker meanings, sentence meanings, implicatures, presuppositions, etc. Lexicography investigates nouns, verbs, words, their stems, definitions, forms, pronunciations, origin.

word-form when it would be expected, all else being equal, to possess such a word-form. In English, an example is in the paradigm of the verb STRIVE, which for most speakers lacks a past/passive participle, or at least there is a significant lack of consensus on what it should be: ?*striven*, ?*strove*, ?*strived*. Linguistic Reality

L Wetzel, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Linguistic reality is that portion or aspect of reality that linguistics seeks to understand and explain, and in virtue of which true linguistic claims are true. Linguistics is the scientific study of language, its units, nature, and structure. To see what the units, nature, and structure of language are, we should look to what linguists say. A reasonable place to begin is *An encyclopedia of language*. It reveals that in addition to languages and language users, phonetics cuts up linguistic reality into vowels, consonants, syllables, words, and sound segments, the human vocal tract and its parts (the tongue has five), among other things (*see* **Phonetic Pedagogy**). Phonology is also concerned with sounds, but organizes them in terms of phonemes, allophones, alternations, utterances, phonological representations, underlying forms, syllables, words, stress-groups, feet, and tone groups (*see* **Phonology: Overview**). In grammar, morphology describes morphemes, roots, affixes, and so forth, and syntax analyzes sentences, semantic representations, LF representations, among other things (*see* **Grammar**). Semantics studies signs, their meanings, their sense relations, propositions, etc. Pragmatics deals with speech acts, speaker meanings, sentence meanings, implicatures, presuppositions, etc. Lexicography investigates nouns, verbs, words, their stems, definitions, forms, pronunciations, origin.

Why Those Objects?

What is the linguist's justification for positing, or recognizing, vowels and consonants, phonemes, morphemes, words, sentences and so on? A general though unhelpful answer is that countenancing such objects produces theories that have a great deal of classificatory, explanatory, and predictive power. The more specific question 'but why posit phonemes?' must be justified within phonology by comparing a theory with phonemes to one without, as must the more specific question of why [b] and [p] are phonemes of English. Why certain noises are enshrined as dictionary entries needs to be justified within lexicographical methodology, rather than, say, within philosophy. The point is that the justification is to be found within linguistic theory, and in most cases within a particular subdiscipline, since subdisciplines have different assumptions. (Phonetics and phonology approach the sound signal differently and hence parse it in terms of different units. Lexicography might give credence to the thesis that all linguistic objects have instances, since each of the million or so words recognized by the *O.E.D.* have been uttered or inscribed by someone at some time. But grammar might not; there are more, perhaps infinitely many more, sentences than will ever be used.) Assuming there is sufficient internal justification for recognizing the existence of the above-mentioned objects, we may now ask the following question.

What Are They?

What, for example, is that quintessential linguistic object an expression? For that matter, what is a language? One answer to the former would be that an expression is anything that is a noun, verb, adjective, etc., or a sequence of such things built up by means of the grammatical rules. But that merely raises the question of what these other things are. Obviously, nouns and verbs are for the most part **words**, but what are words? Are they physical objects, particular events, abstract objects, kinds, classes, or mental entities? (Parallel questions may be asked of languages: are they social practices, abstract objects, classes of expressions, or psychological products of the language faculty? While it is beyond the scope of this short encyclopedia article to address the more complicated question about language, it is worth noting that the proposed answers mirror those given below on what a word is.)

Types and Tokens

Before such questions can be tackled, we have to disambiguate the word 'word,' which could mean either 'word type' or 'word token.' There is only one definite article in English, the word 'the' – the word type – but there are millions of the's on pages in the Library of Congress and the lips of members of Congress – the word tokens (*see* **Type versus Token**). Word tokens are particulars; they might be composed of ink, sounds, or smoke signals. They have a unique spatiotemporal location, unlike types. Types are unique but capable of more than one instantiation or representation, unlike their tokens. A good indicator that there are both types and tokens is the different counting procedures associated with the same word. When it is said that an educated person's vocabulary is upward of 10 000 words, that there are exactly 26 letters of the English alphabet, or that English has 18 cardinal vowels, types are being counted, since the numbers would exceed a million if we were counting tokens. As the examples suggest, not only words but also vowels, phonemes, letters, utterances, sentences, and most of the rest of the linguistic objects found in our survey come in types and tokens.

Which sorts of objects, then, does linguistics explicitly refer to and quantify over – types or tokens? Types – although linguistics is an empirical science based on empirical data, applicable to particulars – tokens – in the causal realm. Yet to ensure generality in an economical format, most of the references and quantifications that appear in linguistic theory involve types and their relationships to each other. Expressions, for example, may be composed of words, and words composed of syllables, and syllables of phonemes, and phonemes of features – all of which are types. (This might be thought puzzling; how can an expression such as 'Pease porridge hot, pease porridge cold' be six words long, if there are only four words, each of them unique, of which it might be composed? For a resolution of this puzzle, (*see* **Type versus Token**). Linguistics, in other words, is awash in references to and quantifications over types, including words. Our original question then becomes the following one.

What Are Word Types?

It should be clear that word types (hereafter: words) are not particular physical objects/events, but it remains to be seen whether they are abstract objects, kinds, classes, or mental entities – or perhaps whether they do not exist at all.

Even among word **types**, there are several sorts of words. Yet one of the lexicographer's uses of the word 'word' stands out. A rough characterization of this sort is *the sort of thing that merits a dictionary entry.* (*Rough*, because some entries in the dictionary, e.g.,

il-, *-ile*, and *metric system* are not words, and some words, e.g., place names and other proper names, do not get a dictionary entry.) To fix our thoughts on what an account must explain, let us consider the word *color*, or *colour*. According to the *O.E.D.*, the noun *color* is from early modern English, is pronounced [kʊˈlər] has two 'modern current or most usual spellings' [colour, color]; 18 earlier spellings [collor, collour, coloure, colowr colowre, colur colure, cooler, couler, coullor, coullour, coolore, coulor, coulore, coulour, culler, cullor, cullour]; and 18 different senses – divided into four branches – with numerous subsenses. The verb *color* is a different word, but with the same pronunciation and spellings (*O.E.D.*, vol. 2: 636–639). *Webster's* assures us that the word *schedule* has four current pronunciations: ['ske-(,)jü(ə)l], ['ske-jəl] (US), ['she-jəl] (Can.) and ['she-(,)dyü(ə)l] (Eng.) (*O.E.D.*, vol. 2: 1044). Thus, a word can be written or spoken; it can have more than one correct spelling, more than one correct spelling at the same time, more than one sense at the same time, the same correct spelling and pronunciation as a different word; and lastly, a word may have more than one correct pronunciation at a given time. These linguistic facts have to be accommodated by any account of words.

Realism

Probably the most popular account of words is given by platonic realism: words are abstract objects – acausal objects, like numbers, that have no spatiotemporal location. As can be seen from the preceding paragraph, they are very abstract entities indeed, for there is no relatively simple property, like spelling or pronunciation or meaning, that all tokens of the word *color* have in common; not even all their written tokens have the same correct spelling. (Indeed, the realist may argue that that is one of the primary justifications for positing word types – being a token of the word *color* might be the only glue that binds the considerable variety of space-time particulars together). This should discourage the misconception that realism is committed to a platonic 'form' (the spelling, say) that all instances resemble the way a cookie resembles a cookie cutter (although the old view lives on in the fact that spellings are called 'forms' of the word). Family resemblance in the standard cases is the most that might be hoped for, but intentionality and context are such important factors in determining what type a token is a type of, that even resemblance can fail in nonstandard cases. (It should be noted, if it is not already clear from the foregoing, that a physical object that is a token of a type is not one **intrinsically** – merely by being a certain sequence of shaped ink marks, say. It is only a token relative to a type, a language, and perhaps an orientation. Moreover, it may need to have been produced with a certain intention and in accordance with certain conventions.)

Platonic realism, whether of words or any other abstract objects, must face a serious epistemological challenge, namely, to explain how it is that spatiotemporal creatures such as ourselves can have knowledge of these abstract things if we cannot causally interact with them. Admittedly, we do causally interact with word tokens, but if the tokens are as diverse as was emphasized above, how do we arrive at the properties of the type at all? There are various realist responses to this problem (responses that are not necessarily mutually exclusive). One is to appeal to intuition. Another is to claim that just as maps represent a city, so tokens represent their types, thus reducing the problem to one of characterizing representation. Another is to reject platonic realism altogether in favor of Aristotelian realism. This involves dropping the claim that words have no spatiotemporal location, and claiming instead that they have many such locations; each type is 'in' each of its tokens. Such a position suggests that there could not be an uninstantiated type. While plausible for words, it is not plausible for sentences. A third response is to claim that words are kinds, just as species are, thus reducing the problem of how we arrive at knowledge of types to one of induction.

Conceptualism

As the terms 'platonic' and 'Aristotelian realism' suggest, we have run into the old philosophical problem of universals in virtue of the fact that types have instances. Not surprisingly, the same camps are in evidence here. The traditional opponents of universals/abstract objects were the conceptualists and the nominalists. The conceptualists argued that there are no general things such as *man*; there are only general *ideas* – that is, ideas that apply to more than one thing. Applied to words, the thesis would be that words are not abstract objects 'out there,' but objects in the mind. Their existence then, would be contingent on having been thought of. While this contingency may have a good deal to recommend it in the case of linguistic items, by itself conceptualism is just a stopgap measure. For ideas also appear to come in types and tokens (as evidenced by the fact that two people sometimes have the same idea). So either the conceptualist is proposing that word types are idea types – which would be a species of realism – or she is proposing that there are no types, only mental particulars in particular persons, which is a species of nominalism.

Nominalism

The problem for those hostile to universals and abstract objects is to account for our apparent theoretical commitment to types, which are clearly not spatiotemporal particulars. Traditional nominalists argued (as their name implies) that there are no general things, there are only general words, which apply to more than one thing. But this too is not a solution to the current problem, presupposing as it does that there are word types – types are the problem.

Class nominalists have proposed that a word type is just the class, or set, of its tokens. But this is unsatisfactory because, first, classes are abstract objects too, so it is hard to see how this is really a form of nominalism about abstract objects. And second, classes are ill-suited for the job, since classes have their membership and their cardinality necessarily, but how many tokens a word has is a contingent matter. (One less token would not annihilate the word.)

Initially more promising is the nominalistic claim that talk of types is harmless because it is unnecessary – it is just shorthand for talk of tokens. *The mountain lion is a mammal* is easily translated as 'every mountain lion is a mammal.' So to refer to the noun *color*, say, we need only refer instead to all its tokens. One problem is how to do this. We can't say 'every token of the noun "color"... ,' because 'color' refers to a type. And 'every noun "color"...' does not seem grammatical, a fact that is even more apparent if we consider sentences (e.g., 'every "the cat is on the mat"...'). Even if we could, truths will convert to falsehoods (using the 'every'-conversion). The noun *color* is pronounced [kɒ'lər], but particular inscriptions of it are not audible at all. So the question is how we might identify these tokens grammatically but without referring to the noun *color* itself and still say something true and (in some appropriate sense) equivalent. The idea seems to be that the type must embody certain similar features that all and only its tokens have. This is a beguiling idea, until one tries to find such a feature, or features, amid the large variety of its tokens – even the well-formed tokens. Consider *color* and *schedule* again. They demonstrate that neither same spelling, same sense, nor same pronunciation prevail. As the preeminent nominalist Goodman observed, "Similarity, ever ready to solve philosophical problems and overcome obstacles, is a pretender, an impostor, a quack .... Similarity does not pick out inscriptions that are 'tokens of a common type' .... Only our addiction to similarity deludes us into accepting similarity as the basis for grouping inscriptions into the several letters, words, and so forth" (Goodman, 1972: 437–438).

Further undermining the reductive approach being considered is that each of the possible defining features mentioned (e.g., spelling, pronunciation) involve reference to types: letter types in the spellings, phoneme types in the pronunciation. (Types are defined in terms of each other.) These too would have to be analyzed away in terms of quantifications over particulars. If, as a last resort, one were to specify a massive disjunction that avoided all references to types, one that captured each and every token of the noun *color*, one would capture tokens of other words, too. Paraphrasing quantifications over word types would be extraordinarily difficult. The moral is that whatever word types are, they are indispensable.

Linguistic Rights

T Skutnabb-Kangas, Roskilde Universitetscenter, Roskilde, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Central Concepts

All the rights that individuals, groups, organizations, and states have in relation to languages (their own or others) are linguistic rights or language rights (LRs). Languages may similarly have rights. Strictly speaking, only binding rights (coded in laws or regulations of various kinds) count. In most cases, these also include a duty-holder who has to see to it that the rights can be enjoyed. A state or a regional authority can, for instance, have the duty to organize education through the medium of a certain language for certain individuals or groups in a specific place. In addition to rights proper, there are many nonbinding recommendations, declarations, and other nice intentions and wishes about LRs.

An individual in a specific country may have the right to use her or his mother tongue in various contexts, for instance in dealing with authorities, local, regional, or state-wide, orally or in writing or both; the authorities do not necessarily need to reply in the same language. The mother tongue is often for legal purposes defined in a strict way, as the first language that a person learned, and still speaks, and with which s/he identifies. A definition often used in situations where forced assimilation of indigenous peoples has made the older generation speak the dominant language to their children, is sometimes much less strict: a mother tongue, with LRs connected to it, is defined as a language which is, or has been, the first language of the individual her-/himself, or of (one of) the parents or grandparents.

Often, it depends on how many individuals there are in a country (area, region, municipality, etc.) whether individuals (speakers or signers) belonging to that group have any LRs; the group has to have a certain size. Two of the most important European LRs documents, from the Council of Europe, use group size as a criterion, but do not in any way define it: The European Charter on Regional or Minority Languages, and the Framework Convention on the Protection of National Minorities, both in force since 1998, use formulations such as "*in substantial numbers*" or "*pupils who so wish in a number considered sufficient*" or "*if the number of users of a regional or minority language justifies it*." (See the latest news about these documents and their ratifications at the Council of Europe. The treaty numbers are 148 and 158).

If an individual can use the right to all mother tongue medium services anywhere in her or his country, we speak of a principle of personality. Usually, only members of large groups with excellent protection have this kind of right, which in most cases is restricted to the dominant language speakers in a country. Often, such speakers are not even aware of how precious these rights are, and how unusual it is to possess such rights for any of the world's linguistic minorities (or even some linguistic majorities: e.g., in several African countries, the old colonial languages still have more rights than the indigenous African languages have). If LRs are connected to a specific region, such as is the case in Switzerland, where German-speakers can use their language in official contexts only in certain cantons, while French, Italian, or Romansch-speakers can use their respective languages only in certain other cantons (where German speakers do not have the right to use German), we speak of a principle of territoriality. That means in practice that if Italian-speaking Swiss parents want their children to be educated through the medium of Italian, they have to live in the only canton (Tessin) where this is a right.

Many international organizations and most states have language policies that spell out the official languages of the organization or state and, by implication, the LRs of the people, groups, and states dealing with, and working within, that entity. The United Nations has six official languages, the Council of

Central Concepts

All the rights that individuals, groups, organizations, and states have in relation to languages (their own or others) are linguistic rights or language rights (LRs). Languages may similarly have rights. Strictly speaking, only binding rights (coded in laws or regulations of various kinds) count. In most cases, these also include a duty-holder who has to see to it that the rights can be enjoyed. A state or a regional authority can, for instance, have the duty to organize education through the medium of a certain language for certain individuals or groups in a specific place. In addition to rights proper, there are many nonbinding recommendations, declarations, and other nice intentions and wishes about LRs.

An individual in a specific country may have the right to use her or his mother tongue in various contexts, for instance in dealing with authorities, local, regional, or state-wide, orally or in writing or both; the authorities do not necessarily need to reply in the same language. The mother tongue is often for legal purposes defined in a strict way, as the first language that a person learned, and still speaks, and with which s/he identifies. A definition often used in situations where forced assimilation of indigenous peoples has made the older generation speak the dominant language to their children, is sometimes much less strict: a mother tongue, with LRs connected to it, is defined as a language which is, or has been, the first language of the individual her-/himself, or of (one of) the parents or grandparents.

Often, it depends on how many individuals there are in a country (area, region, municipality, etc.) whether individuals (speakers or signers) belonging to that group have any LRs; the group has to have a certain size. Two of the most important European LRs documents, from the Council of Europe, use group size as a criterion, but do not in any way define it: The European Charter on Regional or Minority Languages, and the Framework Convention on the Protection of National Minorities, both in force since 1998, use formulations such as "*in substantial numbers*" or "*pupils who so wish in a number considered sufficient*" or "*if the number of users of a regional or minority language justifies it*." (See the latest news about these documents and their ratifications at the Council of Europe. The treaty numbers are 148 and 158).

If an individual can use the right to all mother tongue medium services anywhere in her or his country, we speak of a principle of personality. Usually, only members of large groups with excellent protection have this kind of right, which in most cases is restricted to the dominant language speakers in a country. Often, such speakers are not even aware of how precious these rights are, and how unusual it is to possess such rights for any of the world's linguistic minorities (or even some linguistic majorities: e.g., in several African countries, the old colonial languages still have more rights than the indigenous African languages have). If LRs are connected to a specific region, such as is the case in Switzerland, where German-speakers can use their language in official contexts only in certain cantons, while French, Italian, or Romansch-speakers can use their respective languages only in certain other cantons (where German speakers do not have the right to use German), we speak of a principle of territoriality. That means in practice that if Italian-speaking Swiss parents want their children to be educated through the medium of Italian, they have to live in the only canton (Tessin) where this is a right.

Many international organizations and most states have language policies that spell out the official languages of the organization or state and, by implication, the LRs of the people, groups, and states dealing with, and working within, that entity. The United Nations has six official languages, the Council of

Europe only two (English and French). The European Union has several times increased the number of its official languages, such that after its latest expansion, in May 2004, the Union now has 20 official languages; all official documents have to be made available in all of them. Many organizations also have working languages; their number may be more restricted. A number of states have only one official (or state) language; most have two or more (English is *an* official language in more than 70 states; see Skutnabb-Kangas, 2000). South Africa has 11 official languages, India 22. In addition, many states specify one or several national, additional, link, or national heritage languages in their constitutions; in most cases, these have fewer rights than the official languages have (see de Varennes, 1996).

Linguistic Human Rights (LHRs)

The very recent and still somewhat unclear concept of Linguistic Human Rights (LHRs) combines language rights (LRs) with human rights (HRs). LHRs are those (and only those) LRs which, first, are necessary to satisfy people's basic needs (including the need to live a dignified life), and which, second, therefore are so basic, so fundamental that no state (or individual or group) is supposed to violate them. Some basic rights prohibit discrimination on the basis of language (negative rights); others ensure equal treatment to language groups (positive rights). There are many LRs which are not LHRs. It would, for instance, be nice if everybody could, even in civil court cases, have a judge and witnesses who speak (or sign) this person's language, regardless of how few users the language has. Today, it is mostly in criminal cases only that one has a linguistic HUMAN right to be informed of the charge against oneself in a language one understands (i.e., not necessarily the mother tongue); in all other contexts, people may or may not have a LANGUAGE right, depending on the country and language; in the best cases, interpreters paid for by the state are used. Likewise, it would be nice if the following demands were to be met:

> All language communities are entitled to have at their disposal all the human and material resources necessary to ensure that their language is present to the extent they desire at all levels of education within their territory: properly trained teachers, appropriate teaching methods, textbooks, finance, buildings and equipment, traditional and innovative technology.

But such demands are completely unrealistic and cannot be considered part of LHRs. (They come from Article 25 of the 1996 Draft Universal Declaration of Linguistic Rights.) At this moment, only a few dozen language communities in the world have these kinds of rights; this has to be seen against the background of the fact that there are some 6500 to 7000 spoken languages (and perhaps an equal number of sign languages) in the world (see Ethnologue; see Skutnabb-Kangas, 2000, Chapter 1, for the unreliability of the statistics).

Two kinds of interest in LHRs can be distinguished. One is "the expressive interest in language as a marker of identity," the other an "instrumental interest in language as a means of communication" (Rubio-Marín, 2003: 56). The expressive (or noninstrumental) language rights "aim at ensuring a person's capacity to enjoy a secure linguistic environment in her/his mother tongue and a linguistic group's fair chance of cultural self-reproduction" (Rubio-Marín, 2003: 56). It is only these rights that Rubio-Marín calls "language rights in a strict sense" (Rubio-Marín, 2003: 56); in other words, these could be seen as LHRs. The instrumental language rights "aim at ensuring that language is not an obstacle to the effective enjoyment of rights with a linguistic dimension, to the meaningful participation in public institutions and democratic process, and to the enjoyment of social and economic opportunities that require linguistic skills" (Rubio-Marín, 2003: 56). So far, it is not at all clear what should and what should not be considered LHRs, witness the lively ongoing debates about the topic.

Language is one of the four most important human characteristics (among many others that are also listed in human rights instruments) on the basis of which discrimination is never allowed (the others are gender, 'race,' and religion). Still, language often disappears in the educational paragraphs of binding HRs instruments. One example: the paragraph on education (§ 26) of the Universal Declaration of Human Rights (1948) does not refer to language at all. Educational linguistic human rights, especially the right to mother tongue medium education, are among the most important rights for any minority. Without them, a minority whose children attend school, usually cannot reproduce itself as a minority: it cannot integrate with the majority, but is forced to assimilate to it.

Binding educational clauses of human rights instruments have more opt-outs, modifications, alternatives, etc., than other Articles of such instruments have. One example is the UN Declaration on the Rights of Persons Belonging to National or Ethnic, Religious and Linguistic Minorities in 1992 (emphases added: '*obligating*' and positive measures in *italics*, '**opt-outs**' in **bold**):

A. States *shall protect* the existence and the national or ethnic, cultural, religious, and linguistic identity of minorities within their respective territories, and *shall encourage* conditions for the *promotion* of that identity.
B. States *shall adopt* **appropriate** legislative *and other* measures *to achieve those ends*.

. . .

4.3. States **should** take **appropriate** measures so that, **wherever possible**, persons belonging to minorities have **adequate** opportunities to learn their mother tongue **or** to have instruction in their mother tongue.

The Council of Europe's *Framework Convention for the Protection of National Minorities* and *The European Charter for Regional or Minority Languages*, both in force since 1998, also have many of these modifications, alternatives, and opt-outs. The Framework Convention's education Article reads as follows (emphasis added):

> In areas inhabited by persons belonging to national minorities traditionally or in substantial numbers, **if there is sufficient demand**, the parties shall **endeavor** to ensure, **as far as possible** and **within the framework of their education systems**, that persons belonging to those minorities have **adequate** opportunities for being taught in the minority language **or** for receiving instruction in this language.

The opt-outs and alternatives ('claw-backs') in the *Charter* and the *Convention* permit reluctant states to meet the requirements in a minimalist way, something they can legitimize by claiming that a provision was not 'possible' or 'appropriate,' or that numbers were not 'sufficient' or did not 'justify' a provision, or that it 'allowed' the minority to organize teaching of their language as a subject, but at their own cost.

Without binding educational linguistic human rights, most minorities have to accept 'subtractive' education through the medium of a dominant/majority language. In subtractive language learning, a new (dominant/majority) language is learned at the cost of the mother tongue, which is displaced, leading to diglossia and often to the replacement of the mother tongue. Diglossia means a situation with functional differentiation of languages, e.g., one at home and in the neighborhood, another for use at school and with authorities.

Assimilationist, subtractive education of indigenous and minority children is genocidal; it fits two of the five definitions of genocide in the *UN International Convention on the Prevention and Punishment of the Crime of Genocide* (E793, 1948):

Article II(e): "forcibly transferring children of the group to another group," and
Article II(b): "*causing serious bodily or* ***mental*** *harm to members of the group*"(emphasis added; see Skutnabb-Kangas, 2000 for details).

The human rights system should protect people in the globalization process, rather than give market forces free range. Human rights, especially economic and social rights, are, according to human rights lawyer Katarina Tomasevski (1996: 104), supposed to act as *correctives to the free market*. She claims that "The purpose of international human rights law is . . . to overrule the law of supply and demand and remove pricetags from people and from necessities for their survival." These necessities for survival thus include not only basic food and housing (which would come under economic and social rights), but also basics for the sustenance of a dignified life, including basic civil, political, *and cultural* rights. It should, therefore, be in accordance with the spirit of human rights to grant people full linguistic human rights.

Linguistic Terminology

J B Walmsley, Universität Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

> A precise terminology is a *conditio sine qua non* if one wants to understand grammatical facts.... (Jespersen, 1924: 315)

The terminology of a discipline consists of a set of concepts structuring the field, together with the labels associated with the concepts. Linguistic terminology is the terminology we use to describe the object 'language.' The study of linguistic terminology thus lies on the one hand at the intersection between terminology research in general (terminology science, terminology management, history of terminology, terminographical recording, etc.), and the study of language, or linguistics, on the other – linguistics being, as Firth remarked, nothing other than language turned back on itself.

As objects of description, natural languages are unique in that, so far as we know, they all contain within themselves the resources they need to refer to themselves and to the ways in which they are used (Lyons, 1980: 293). Native speakers have the means to talk about their own language, speech, failures in communication, etc., as objects of discourse, and this ability appears to be a skill that children acquire as part of the natural process of language acquisition (Gombert, 1997). Seen from this perspective, any linguist wanting to provide a comprehensive account of the syntax and semantics, and even the pragmatics, of 'a language,' must also provide an account of its metalinguistic terms and uses.

In discourse about the object 'language,' terminology needs to be distinguished both from the metalinguistic discourse of which it is a subpart, and from the (partly overlapping) 'nomenclature' (names for concepts): a nomenclature can be a list of names, whereas a terminology is a set of systems and subsystems of names.

Interest in the metalinguistic functions of language in the Anglo-Saxon world has mainly concentrated on such things as type-token relations, token reflexivity, and the study of propositions (such as the truth conditions of sentences like 'This sentence is false'). But metalinguistic uses of natural languages pervade much more extensive areas of everyday discourse. The boundary between the use of a natural language as a metalanguage for everyday purposes and its use for technical descriptive or theoretical purposes is not always easily drawn. This can be illustrated in simple, everyday terms: What is the meaning of 'word' in 'English has a vocabulary of half-a-million words,' or in 'This dictionary contains 55 000 words'?

From a terminological point of view, the English lexicon contains different kinds of words (or, preferably, 'lexemes'): lexemes whose function is almost entirely restricted to their technical use ('adjective,' 'infinitive,' 'deixis'), lexemes that have both a technical sense and a less-well-defined everyday sense ('word,' 'voice,' 'gender'), and the vast majority of other lexemes, which do not form part of the linguistic terminology.

The problems arise with the first two categories, and it is this that distinguishes the terminology of linguistics from terminologies in the natural sciences. In the more mature natural sciences, terminology has kept pace with scientific developments, and it is based on widespread agreement as to the nature and status of the concepts concerned. Such agreement does not exist in linguistics. (For example, how many parts of speech are there? Should they be called 'form classes,' 'word classes,' or even 'lexeme classes'? How many tenses does English have?) The evidence suggests that terminological agreement in linguistics is becoming less rather than more likely. Linguistic terminology thus faces three major problem areas: the categories underlying the terminology, the terms themselves, and the proliferation of terms, leading to the 'translation problem.'

Attempts to deal with these problems have followed two major routes: normative or descriptive. Those taking the normative route seek to change the terminology either radically (Barnes, Fries) or by tinkering with it (Sonnenschein, Jespersen). Those taking the descriptive route write dictionaries of linguistic terminology (Nash, Gibbon).

Between about 1885 and 1950, the simplification and harmonization of terminology was a topic of particular interest to linguists worldwide. With the foundation of the Birmingham Grammatical Society in 1885, Sonnenschein initiated a campaign to simplify and harmonize the terminologies of the main foreign languages taught in schools. The most significant outcome of this movement was the publication of the *Parallel grammar series* – a set of textbooks that ultimately comprised more than 25 volumes covering eight languages. The success of this series helped to stimulate similar work in other countries, which Sonnenschein tried to coordinate on an international scale. These efforts culminated in the publication of schemes of terminology for France (1910), England and Wales (1911), and the United States (1913) (Walmsley, 2001). Terminology became one of the main themes at the Sixth International

Congress of Linguists, Paris, 1948, and was also one of Fries' targets (1952). Nevertheless, none of the normative proposals seems to have enjoyed significant success.

The argument against the traditional Latinate terminology is that it invites the grammarian to press his or her description of a language into categories to which it is not suited. There is no *a priori* reason why the terminology should work like this. In principle, four strategies are available to us: we can invent new terms but apply them to the conventional categories; we can retain the conventional nomenclature but establish new categories; we can postulate new categories and devise a new terminology to go with them; or we can stick with the conventional categories and the old nomenclature. (This last option would be one way of viewing what we think of as 'traditional grammar.')

To first address the problem of the categories (as opposed to their labels), the evidence shows that adopting the traditional categories of Latin grammar did indeed have a decisive influence on the history of English grammaticography. Levin described as a "fallacy . . . discussing the grammar of English on the basis of preconceptions derived from the grammar of another language (say Latin)" (Levin, 1960: 262). Following Levin, Crystal complained, "Often a grammarian would take over and work within a traditional frame of reference assuming that it was satisfactory for his purposes . . . a more conscious awareness of linguistic principles would have shown that it was not; . . . the best example . . . [of this is] . . . the attempt to describe modern languages as if they were variants of Latin" (Crystal, 1971: 69).

Despite such admonitions, concepts not appropriate to – or even non-existent in – present-day English continue to be taught in introductory textbooks and teaching grammars, among them voice, case, a future tense, and subjunctive mood. As long ago as 1922, McKerrow, for instance, wrote, "if we were now starting for the first time to construct a grammar of modern English, without knowledge of or reference to the classics, it might never occur to us to postulate a passive voice at all" (McKerrow, 1922: 163; cf. Andersen, 1991). It is sometimes claimed that English nouns have 'only' two cases and that some pronouns have a distinctive form when used as objects (an 'objective,' i.e., accusative, form). Of the latter, Sweet wrote: "the so-called accusative of the personal pronoun is functionally not a case at all . . . The real difference between 'I' and 'me' is that 'I' is an inseparable prefix used to form finite verbs, while 'me' is an independent or absolute pronoun, which can be used without a verb to follow" (Sweet, 1875–1876: 495; cf. Hudson, 1995).

The limitations of the traditional core of terminology also mean that categories that could – or should – be recognized in English go unlabeled, or even unidentified. If we set up a table of the modal verbs (*can, could, may, might, must, shall, should, will, would*), for instance, we find that traditionally we have names for some syntagms (*will go*, 'future'; *should go,* 'subjunctive'), but not for others. "Why should the combinations *would go* and *would have gone* have special terms rather than *might go* and *might have gone*, or *dared go*, etc.? The only reason is that these forms serve to translate simple tense-forms of certain other languages" (Jespersen, 1924: 281).

Observations such as these would seem to justify the Structuralists' criticisms of earlier grammarians. Nevertheless, the evidence shows that earlier grammarians, far from being the ill-informed, complacent practitioners pictured by Crystal *et al.*, were well aware of the difficulties inherent in changing the categories and the nomenclature: "there is probably no language so different from the English as the Latin is . . ." (Ward, 1767: iv); "if an English Grammar were to be made for the sole Purposes of those who propose to learn, and to use no Language but the English only, it might be put into a different Form from that of the Grammars of the learned Languages" (Ward, 1767: vii). The problem Ward saw was that to the extent that we set up categories and terminologies outside the Latin tradition, we create difficulties in cross-linguistic comparison. And it was this cross-linguistic comparability that earlier grammarians exploited when they first began to teach Latin through the medium of English in the 14th century (Walmsley, 2004). Since much of the teaching was done through translation, it is not surprising that pupils were taught to discover in English exactly those categories that already existed in Latin. And when the first grammar of English to be written in English – William Bullokar's – appeared about two centuries later (Turner, 1980), again, it was not ignorance that induced the author to model his description so closely on Latin; rather, it was his desire to prove that English, too, could be ". . .'a perfect ruled tongue, / conferable to grammar art / as any ruled long'. English [was] as orderly and subjectable to grammatical rules as any language that has been the object of prolonged teaching" (Robins, 1994: 21).

Concerning the names for the concepts, grammarians have been criticized for "obscuring the grammatical requirements of English by discussing facts of English form in the vocabulary designed to codify Greek and Latin" (Dinneen, 1967: 170) – in other words, for using Latinate labels for the concepts. Again, earlier grammarians were not unaware of the problem: "It has been asserted . . . that in order to

produce a complete Grammar of our language, we should imitate the Latin in the formation of our Cases, Moods, and Tenses; whilst others … affirm that the English tongue has no similitude whatever with the Latin in this respect, and therefore they are for preventing our making use of the common technical terms usually employed in Grammars of our language" (Goldsmith, in Wiseman's *Complete English Grammar*, 1764: Preface; quoted in Michael, 1970: 502–503).

The difficulty lies in finding appropriate alternative terms. This has not prevented reformers from proposing 'native' English alternatives to terms of Latin origin. Barnes (1878), for instance, included a list of native alternatives for more than 350 Latinate words, including terms for grammar. But it is difficult to see what advantage a native terminology brings, if coupled to the traditional categorial framework.

The most radical attempt to break out of the system was that of Fries (1952). On the basis of strictly distributional criteria, he postulated four major parts of speech and 15 classes of function words, which he labeled 1–4 and A–O, respectively. Fries warned against equating his word classes with those of traditional grammar: "The reader, familiar with the conventional grammar, will probably attempt … to equate these class numbers with the usual names, 'nouns,' 'verbs,' 'adjectives,' and 'adverbs' … If he does, he will certainly find increasing difficulty in the following chapters" (Fries, 1952: 87; cf. Fries, 1952: 2). Fries's scheme, however, did not succeed in replacing the old Latinate terms – testimony to the robustness of the traditional terminology.

The third and final problem area concerns the proliferation of linguistic terminologies. The 20th century saw an unprecedented increase in the number of grammatical theories. The interested customer could choose from about 50 or 60 theories of grammar. These theories frequently draw the boundaries between themselves and neighboring theories in part at least by means of their terminology. Here, as elsewhere, it is not simply a question of choosing a new label for the same concept: if a term has a place in a different system, it becomes a different concept. 'Subject' does not mean the same thing in a system in which it is a primitive as it does in a system in which it is a derived category, as is the case in Government-(and)-Binding (GB) theory.

The proliferation of grammar theories leads to an apparent paradox: if each theory has its own terminology – either introducing new terms or redefining old ones – how is it that linguists of different persuasions can communicate with one another? The language of any specific theory can be viewed as a sort of sub-metalanguage. Linguists recognize when a colleague is 'speaking GPSG,' for instance, and informal translations are not infrequently provided to make the theory comprehensible to linguists of other schools. For example, 'To put the same thing in HPSG terms …' or 'In Cognitive Grammar terms, this would be … .' For understanding to take place, linguists must be as familiar as possible with both theories, and specifically with the points of difference between them. When the adherent of one theory speaks to one of a different persuasion, the hearer needs to make ongoing adjustments – that is, make a sort of mental translation – to the running text, to take account of the differences.

The current core of traditional linguistic terminology is defective insofar as it perpetuates the description of categories not attested in the languages being described and makes other categories invisible or difficult to identify. It does not reflect the individuality of specific languages, nor is it flexible in the sense of being easy to modify. It does, though, offer a coherent system as a basis for comparing languages, and "what is generally referred to as 'traditional grammar' … is much richer and more diverse than is often suggested in the cursory references made to it by many modern handbooks of linguistics" (Lyons, 1968: 3). In this function, the core terms act rather like empty shells or cases into which the particular sub-metalinguistic meanings for individual theories can be inserted. Further terms are added as the theory requires. From a different perspective, the lack of flexibility reveals itself as a remarkable robustness, both synchronically and through time. Provided that certain conditions are met, the terminology permits communication across theories and across languages (typology). Similarly, it facilitates accessibility to linguistic theories and descriptions over a long period of western cultural history. Its core of traditional terms is thus part of the glue that holds the discipline of linguistics together: without this common terminological core, the discipline would fragment into a myriad of mutually unintelligible metalanguages.

Beginning in the late 11th century, language study was divided between pedagogical grammar, instructing nonnative speakers in Latin literacy and speaking, and theoretical (speculative) grammar, which explored the causes of imposition, modes of signification, and the relations between language, concepts, and reality. Linguistic theory was developed in commentaries on Aristotle and Priscian and treatises on universal grammar. More than Alcuin and other Carolingian grammarians, late medieval 'higher grammar' expanded logical approaches to language and grammar by making greater use of Priscian's *Institutiones grammaticae* (cf. 500) and newly available Aristotle texts (*Metaphysics, Sophistical Refutations*) along with the 'old logic' (*De interpretatione, Categories*, *Topics*).

Late medieval linguistic theory combined ancient logical and grammatical approaches to language, with Latin as the exemplar. Both Aristotelian logic and Roman grammar maintained a theory of the arbitrary linguistic sign. Aristotle defined language from the point of view of the perceiver, and *De interpretatione* (with Boethius' commentary) became a base text: "Spoken sounds are symbols of affections in the soul, and written marks [are] symbols of spoken sounds . . . Speech is signifying sound, whose parts signify separately as words but not as propositions . . ."; *De interpretatione*, 16a). Aristotle's conceptualist theory of language was fundamental to late medieval linguistic theory. Priscian defined word classes (*partes*) and construction (*oratio*) from the point of view of the speaker: "[Construction is] the comprehension of words in their most appropriate arrangement, with letters combined to form syllables, syllables combined to form words, and words combined to form sentences" (*Inst. gram.*, 17.3). Unlike pedagogical grammarians, Aristotle and Priscian

Linguistic Theory in the Later Middle Ages

M Amsler, University of Wisconsin, Milwaukee, WI, USA

Beginning in the late 11th century, language study was divided between pedagogical grammar, instructing nonnative speakers in Latin literacy and speaking, and theoretical (speculative) grammar, which explored the causes of imposition, modes of signification, and the relations between language, concepts, and reality. Linguistic theory was developed in commentaries on Aristotle and Priscian and treatises on universal grammar. More than Alcuin and other Carolingian grammarians, late medieval 'higher grammar' expanded logical approaches to language and grammar by making greater use of Priscian's *Institutiones grammaticae* (cf. 500) and newly available Aristotle texts (*Metaphysics, Sophistical Refutations*) along with the 'old logic' (*De interpretatione, Categories*, *Topics*).

Late medieval linguistic theory combined ancient logical and grammatical approaches to language, with Latin as the exemplar. Both Aristotelian logic and Roman grammar maintained a theory of the arbitrary linguistic sign. Aristotle defined language from the point of view of the perceiver, and *De interpretatione* (with Boethius' commentary) became a base text: "Spoken sounds are symbols of affections in the soul, and written marks [are] symbols of spoken sounds . . . Speech is signifying sound, whose parts signify separately as words but not as propositions . . ."; *De interpretatione*, 16a). Aristotle's conceptualist theory of language was fundamental to late medieval linguistic theory. Priscian defined word classes (*partes*) and construction (*oratio*) from the point of view of the speaker: "[Construction is] the comprehension of words in their most appropriate arrangement, with letters combined to form syllables, syllables combined to form words, and words combined to form sentences" (*Inst. gram.*, 17.3). Unlike pedagogical grammarians, Aristotle and Priscian

interrogated grammatical metalanguage and criteria for defining linguistic forms.

In the 12th century, William of Conches, Peter Helias, and the anonymous author of the *Glosulae* wrote commentaries on Priscian focusing on the definitions of word classes, syntactic structures, and the relation between sentence meaning (sense) and reference. These Paris-based precursors of the *modistae*, or speculative grammarians, focused on modes of signifying (*modi significandi*), including verbal (grammatical) and extraverbal (semantic) features, to reframe traditional word class definitions. Two decades earlier, Abelard had challenged Aristotelian realism by arguing that modes of signifying and Aristotle's categories (motion, rest, quantity, etc.) were features not of reality but of how language describes reality (*Logica* 116.35–117.2). William and Peter Helias took a different approach. In *Summa super Priscianum* (1140), Helias used the modes of signifying to account for the ontological 'causes' of the parts of speech. Nouns signify substance subsisting in matter and also signify the combination of matter and form. After the original (arbitrary) imposition of nouns to signify substance, people 'enlarged' speech when they used nouns to signify things 'as if' they are substances, 'in the mode of substance (*modo substantiae*) . . . without tense, in a common or proper or almost common or proper manner' (Helias, 1993: 120–21). Verbs signify that which acts or is acted on or semantic primitives 'in the mode of' acting or being acted on, with tense markers (Helias, 1993: 196). Participles share features of nouns and verbs: they signify acting or being acted on through time, but they also deploy the mode of signifying the actor (*agentus*) or the one acted on (*patius*) and thus display nominal signification (Helias, 1993: 449).

In the 13th and 14th centuries, theoretical grammarians known as *modistae*, based in Paris, Bologne, and Erfurt, systematized this reanalysis of the *modi significandi*, parts of speech, and syntactic relations into a complex theory of language and grammar. Like William of Conches and Roger Bacon, *modistae* such as Michel de Marbais (fl. 1240–1290), Boethius of Dacia (fl. 1265–1280), Martin of Dacia (d. 1304), Thomas of Erfurt (fl. 1300), and Siger de Courtrai (d. 1341) argued that grammar was properly concerned with underlying structures common to all languages. Universal grammar is a speculative (theoretical) science that treats the parts of speech as aspects of syntax and procedures for combining words into grammatical sentences (congruity, government) that correspond in some respect to the nature of reality. Unlike pedagogic grammar, the *modistae* used both *auctores* and made-up Latin sentences to illustrate grammaticality. The *modistae* accepted that language is a set of arbitrary signs signifying mental concepts directly and reality only indirectly. They produced a coherent theory of language that systematically linked word class properties with the properties of mental concepts and then with the properties of universals standing behind material instantiations. They took as given the first imposition of names on reality (things, qualities, action); second imposition designates words according to forms and functions in sentences (grammatical difference). Following Aristotle and Porphyry, the *modistae* argued that such impositions could be necessary or arbitrary, depending on the degree of realist correspondence between words and things.

Many speculative grammar treatises and commentaries retain the organization of Priscian's Latin grammar, with sections on orthography (*vox*, *littera, syllaba*), etymology (*partes orationis*), syntax, and prosody, but they add another level to grammatical explanation by exploring the modes of signifying, the causes or rationales for differentiating word classes, and the bases for how each linguistic category relates to mental and external reality. As theoreticians, the *modistae* and their critics were most interested in universal grammar and syntax. Although less concerned with linguistic sound (phonology), some *modistae*, following Aristotle, stated that speech is materially percussed, disturbed air, which is moved by the soul (seat of intellect) using the vocal tract as an instrument. Some speculative grammarians took note of different Latin and vernacular pronunciations or the physiology of articulation (based on Arabic commentaries on Aristotle).

Modistic linguistic theory related word classes to reality and to principles of syntax. The properties of things as they exist (*modi essendi*) are perceived by the intellect and conceptualized as *modi intelligendi*. These perceptions and concepts are reflected in the structures of Latin grammar and expressed in speech through the *modi significandi*, whose formal elements constitute an arbitrary sign system. Spoken words unite voice and meaning (*dictiones*) as signs of concepts. The correspondence of the structure of grammar to the nature of thought and reality can be represented as follows:

THING (*res*) in the world	Properties of the thing (*modi essendi*, 'modes of being')
CONCEPT (*res intellecta*) in the mind	Properties of the concept (*modi intelligendi*, 'modes of understanding')
SIGNIFIED (*res significata*) in the word	Properties of the signified (*modi significandi*, 'modes of signifying')

(from Law, 175)

Because the *modi significandi* directly signify mental concepts and not things themselves, the intellect can also form words that do not correspond to external reality and can attribute to them morphological features of the appropriate word class's modes of signifying (e.g., nouns *chimaera, nullus*).

Modistic syntactic theory was built around the theory of constructions. Every part of speech is ordered to be combinable with others to form a construction. Following Aristotle, the *modistae* argued that every construction is comprised of a subject and a predicate (in contemporary linguistics, NP and VP). Earlier, Helias had distinguished utterance congruity (*congrua voce*) from conceptual congruity (*congrua sensu*) (Helias, 1993: 832). In the 13th century, Boethius of Dacia, contradicting Priscian, argued that impersonal expressions (*fulminat* 'it lightens') are similar to intransitive expressions (*currit*, 'she runs'). Both constructions are imperfectly realized on the level of utterance (*vox*) yet conceptually complete (*secundum intellectum*) because the grammatical subjects are understood (Boethius of Dacia, *Modi*, q. 11, ad. 2, 46–48).

Congruity and *regimen* (government) are the principal features of modistic syntactic theory. Helias defined *regimen* in syntactic terms, while he used *congruitas* in both syntactic and semantic contexts. Congruity demands that (1) two or more words related syntactically agree with the appropriate morphology (gender, number, case, etc.) required by their syntactic functions, or (2) the words convey a conceivable (but not necessarily true) meaning, or (3) both. Thus, constructions can be perfect grammatically and incomplete in sense, or vice versa. Ovid's expression *Turba ruunt* ('the crowd run') illustrates how a sentence can be congruent in sense but not grammatically. *Regimen* determines that one word will 'force' another word to be included in the utterance with a certain case or form in order to complete (perfect) the construction. *Socrates accusat* is a congruent construction in that the subject and verb agree grammatically, but the sentence does not generate a perfect sense because the *regens*, *accusat*, is a transitive verb and determines an object for the perfected construction (see Helias, 1993: 835, 1051).

The *modistae* distinguished at least two grammatical levels for each part of speech, structured by several modes of signifying. The essential *modi significandi* constitute words' being, while accidental modes constitute their inflection. Essential modes are subdivided into general (common to several parts of speech) and specific (particular to an individual part). Nouns and pronouns have in common some modes of signifying in that they "signify by the mode of habit and quietness [stability and permanence]"; verbs and participles "signify by the mode of motion and becoming" (*Sophismata*, I, 43?). At the next level of essential signification, nouns are distinct from pronouns in that nouns deploy 'the mode of determinate apprehension' (qualifying and defining substance); pronouns deploy the 'mode of indeterminate apprehension' (Simon of Dacia, Martin of Dacia). And so forth. The accidental modes of signifying correspond generally to the traditional accidents of Roman grammar. Most accidents establish how an individual part can be used in a construction (*respectivi*, syntactic inflections), but some parts' accidents mark grammatically how the word relates to the modes of being of the things signified (*absoluta*, semantic features such as that the noun *nullus* rather than a verb signifies 'nothing' as a substance) (Thomas of Erfurt, *Gram. spec.*, 150).

The *modistae* developed a strong syntactic theory of transitivity and voice, based on *dependens* (dependency). Every construction has at least one dependent that can have one of two modes of signifying: either the dependent goes to the first constructible or to an element that in turn goes to the first constructible (subject), or the dependent does not go to the first constructible (Martin of Dacia, *Modi signif*, ss. 203–211, 90–94). The theory of transitivity and syntactic firsts and seconds suggests how the *modistae* mostly adopt vernacular and ecclesiastical Latin's SVO word order as *ordo naturalis* ('natural order'), in contrast to *ordo artificialis* ('artificial order,' often inverted word order). The first mode is the principle of an intransitive, the second of a transitive construction. The *modistae*'s use of the terms *transitivus* and *intransitivus*, very different from Priscian's, is based on Aristotle's account of action. In a transitive construction, the action passes into an (direct) object); in an intransitive construction, the action is immanent in the subject. As moderate realists, the *modistae* argued that verbs' grammatical inflections (*currit* = 3rd per. sing. pres.) mark potential action which, depending on the sentence, can either be drawn from the verb and transferred to another constructible or remain immanent in the verb. Thus in the sentence *Socrates legit librum* ('Socrates reads a book'), the relation between the first (subject) noun and the verb is a *constructio intransitiva,* whereas the relation between the verb and the second (object) noun is a *constructio transitiva* in that the action of reading is passed from Socrates to the book (Thomas of Erfurt, *Gram. spec.*, cc. 47–48).

Transitivity and dependency were also key to modistic phrase structure, as the last example sentence indicates. In the sentence *homo albus currit bene* ('the white man runs well'), the adjective and verb depend immediately on the subject noun, while the adverb depends immediately on the verb, which

draws it back to the subject noun. The adjective and the adverb are 'determinants' of the syntactic elements to which they are attached, as marked by inflection or position. The noun phrase *homo albus* is analyzed as an 'intransitive construction of persons' (*constructio intransitivus personarum*), while *homo currit* is analyzed as an 'intransitive construction of acts' (*constructio intransitivus actuum*). According to Radulpus Brito (*Quaestiones super Priscianum minorem*, q. 24) and others, only the latter sort of constructions form propositions. The clause *Si Socrates currit* ('If Socrates runs') is a dependent because the conjunction creates an expectation in the listener that more will follow (Thomas of Erfurt, *Gram. spec.*, c. 54). In modistic theory, the conjunction *si*'s syntactic function is governed by elements outside the dependent clause in which the conjunction occurs. Thus the *modistae* derived the logical structure of propositions from underlying grammar. They did not restrict dependency and transitivity to the level of word class or morphology, but rather argued they are fundamental to construction itself. However, not all *modistae* agreed that every type of word (e.g., conjunction) had a dependency feature that must be closed or perfected in a sentence.

The *modistae* worked out a coherent, sophisticated grammatical theory that exceeded Priscian's largely morphological analysis and established new metalanguage for descriptive parsing and theory of language. Their syntactic theory distinguished surface from underlying structures, material utterance from grammatical congruity and conceptual meaning, form from function, and linear from logical word order. Thus, the *modistae* developed a theory of grammar that increasingly emphasized the autonomy and interrelation of formal, verbal features at the level of both word and sentence. However, some modistic linguistic theory as well as intentionalist critics of the *modistae* relied on the apprehensions of users (speakers, writers, listeners, readers) to complete the sense of an utterance according to internal grammatical rules, constructions of possible meaning, or discursive contexts. *Turba ruunt* might be ungrammatical (lacking subject-verb agreement), but the sense of a crowd as a collective entity makes the sentence comprehensible. *Aqua, aqua* ('Water, water!') might be 'imperfect,' even 'ungrammatical,' but when shouted by someone whose house is afire, the utterance is understandable and effective.

Linguistic Universals, Chomskyan

S Cristofaro, University of Pavia, Pavia, Italy

© 2006 Elsevier Ltd. All rights reserved.

One of the key assumptions of the Chomskyan approach to the study of language is the existence of Universal Grammar, that is, as Chomsky (1976: 29) puts it, a set of principles, rules, or conditions that are elements or properties of all human languages. In fact, as is pointed out by Jackendoff (2002: Ch. 4), the notion of Universal Grammar is used in the literature in three distinct, albeit related, senses. First (for example, in Chomsky, 1965) Universal Grammar has been used to refer to a set of features that all languages have in common. These features can be regarded as universals of language proper, and they are of two types: features pertaining to the types of rules and constraints that have to be present in the grammar, such as phrasal formation rules, derivation rules, and constraints thereon; and features pertaining to the material that provides the basic building blocks of linguistic structure, such as phonological distinctive features in phonology, or parts of speech and the notion of syntactic tree in syntax. In Chomsky (1965) these two feature types are indicated as formal and substantive universals respectively.

The other two senses of the notion of Universal Grammar specifically pertain to the way in which speakers acquire their language. Universal Grammar is also used (for example, in Chomsky, 1972) to refer to the initial state of the mind of a language learner that makes language acquisition possible. This initial state involves knowledge of the complete range of possible human grammars, from which the language learner selects a target grammar in response to the linguistic data to which he or she is exposed. Finally, in its most common sense, Universal Grammar is taken to correspond to the initial state of the mind of a language learner along with the machinery (which Chomsky calls Language Acquisition Device) that makes it possible for the speaker to move from the initial state to the final target grammar.

The notion of Universal Grammar, in its various senses, implies that there are two universal aspects of human language. On the one hand, there is a set of features common to all languages. On the other hand, there is a universal mechanism that makes language acquisition possible. This mechanism crucially involves knowledge of the range of possible grammars, including the features common to all languages, as well as the machinery that allows the language learner to select the target grammar.

The latest versions of generative theory, Principles and Parameters and Minimalism (Chomsky, 1981; Chomsky, 1995), assume that Universal Grammar, intended as the initial state of the mind of the language learner along with the Language Acquisition Device, includes specification of a number of universal principles, each associated with an open value parameter. Individual parameters may have different values in different languages, which are triggered by the linguistic input to which the language learner is exposed. Interaction between the universal principles, the open value parameters, and the input that triggers specific values of these parameters makes it possible for the learner to acquire the target grammar.

The inventory of principles and parameters that are taken to be part of Universal Grammar has evolved over the decades, and different authors take different views. While some authors (e.g., Baker, 2001) have rather elaborate lists of principles and parameters, there has been a general tendency (exemplified, for instance, by Chomsky, 1995 and Jackendoff, 2002) to reduce the inventory of elements posited in Universal Grammar as much as possible, in order to posit the smallest set of elements that can still account for the data.

A classical example of an open value parameter is provided by the so-called head parameter. The head parameter is associated with X-bar theory (Chomsky,

Linguistic Universals, Chomskyan

S Cristofaro, University of Pavia, Pavia, Italy

© 2006 Elsevier Ltd. All rights reserved.

One of the key assumptions of the Chomskyan approach to the study of language is the existence of Universal Grammar, that is, as Chomsky (1976: 29) puts it, a set of principles, rules, or conditions that are elements or properties of all human languages. In fact, as is pointed out by Jackendoff (2002: Ch. 4), the notion of Universal Grammar is used in the literature in three distinct, albeit related, senses. First (for example, in Chomsky, 1965) Universal Grammar has been used to refer to a set of features that all languages have in common. These features can be regarded as universals of language proper, and they are of two types: features pertaining to the types of rules and constraints that have to be present in the grammar, such as phrasal formation rules, derivation rules, and constraints thereon; and features pertaining to the material that provides the basic building blocks of linguistic structure, such as phonological distinctive features in phonology, or parts of speech and the notion of syntactic tree in syntax. In Chomsky (1965) these two feature types are indicated as formal and substantive universals respectively.

The other two senses of the notion of Universal Grammar specifically pertain to the way in which speakers acquire their language. Universal Grammar is also used (for example, in Chomsky, 1972) to refer to the initial state of the mind of a language learner that makes language acquisition possible. This initial state involves knowledge of the complete range of possible human grammars, from which the language learner selects a target grammar in response to the linguistic data to which he or she is exposed. Finally, in its most common sense, Universal Grammar is taken to correspond to the initial state of the mind of a language learner along with the machinery (which Chomsky calls Language Acquisition Device) that makes it possible for the speaker to move from the initial state to the final target grammar.

The notion of Universal Grammar, in its various senses, implies that there are two universal aspects of human language. On the one hand, there is a set of features common to all languages. On the other hand, there is a universal mechanism that makes language acquisition possible. This mechanism crucially involves knowledge of the range of possible grammars, including the features common to all languages, as well as the machinery that allows the language learner to select the target grammar.

The latest versions of generative theory, Principles and Parameters and Minimalism (Chomsky, 1981; Chomsky, 1995), assume that Universal Grammar, intended as the initial state of the mind of the language learner along with the Language Acquisition Device, includes specification of a number of universal principles, each associated with an open value parameter. Individual parameters may have different values in different languages, which are triggered by the linguistic input to which the language learner is exposed. Interaction between the universal principles, the open value parameters, and the input that triggers specific values of these parameters makes it possible for the learner to acquire the target grammar.

The inventory of principles and parameters that are taken to be part of Universal Grammar has evolved over the decades, and different authors take different views. While some authors (e.g., Baker, 2001) have rather elaborate lists of principles and parameters, there has been a general tendency (exemplified, for instance, by Chomsky, 1995 and Jackendoff, 2002) to reduce the inventory of elements posited in Universal Grammar as much as possible, in order to posit the smallest set of elements that can still account for the data.

A classical example of an open value parameter is provided by the so-called head parameter. The head parameter is associated with X-bar theory (Chomsky,

1981), a theory of syntax that assumes a universal principle whereby a phrase always contains a head of the same lexical category (a noun, verb, or preposition) along with possible complements. The head parameter distinguishes between languages in which complements follow the head, as in the English example in (1), and languages in which complements precede the head, as in the Japanese example in (2).

(1) *eat an apple*

(2) Japanese
ringo-o tabe-ru
apple-ACC eat-NONPAST
'eat an apple' (Fukui, 1995: 329)

Depending on the external linguistic input he or she receives, the language learner selects the value 'head-initial' or 'head-final' for the target language. In this way, the universal principle that all phrases contain a head along with possible complements interacts in the learning process with the input about the value of the head parameter in the target language, yielding the correct grammar for the target language.

This model is meant to simultaneously account for universals of language and the actual diversity of languages, as revealed by cross-linguistic investigation. Universals of language are found in the principles and open value parameters that are part of Universal Grammar, while the range of possible values for each parameter determines actual cross-linguistic variation. A similar model is proposed in Optimality Theory (see, e.g., Prince and Smolensky, 1993), where cross-linguistic variation is accounted for by postulating different rankings of a number of universal principles in different languages.

Insofar as it postulates a set of properties common to all languages, and a model to account for actual cross-linguistic variation, the Chomskyan approach is close to the other major approach to linguistic universals, the Greenbergian approach (*see* **Linguistic Universals, Greenbergian**). However, the Chomskyan approach displays a number of distinguishing features.

A major distinguishing feature of the Chomskyan approach involves the status attributed to linguistic universals in terms of mental representation. In the Greenbergian approach, universals are properties holding for all (or a statistically significant part of) human languages, but the theory has no implication as to whether or not these properties are part of a speaker's mental representation of his or her language. In the Chomskyan approach, on the other hand, universals (including both universal principles and open value parameters) have psychological reality, that is, it is assumed that they have specific representations in the human mind. This is a consequence of the explanatory value attributed to universals in this approach. In the Chomskyan perspective, the very reason to postulate linguistic universals in the first place is the need to account for the rapidity and uniformity of language learning. This argument is traditionally known as the 'poverty of the stimulus' argument. It is argued that the primary linguistic data available to the language learner is largely insufficient to construct the target grammar. Therefore, language acquisition would be impossible if the language learner were not endowed with an initial prespecification of the brain specifying the form of the grammar of a possible human language. This prespecification takes the form of the universal principles and parameters that represent the bulk of Universal Grammar. These principles and parameters are ultimately thought to be innate.

Thus, Universal Grammar is basically regarded as an innate toolkit humans are equipped with that makes language acquisition possible. This has two important consequences for the nature of linguistic universals in the Chomskyan theory. First, universals have explanatory value in the theory, in that it is basically assumed that the reason why languages are the way they are is because they reflect a set of universal principles represented in the speaker's mind. This is an example of internal explanation, in that the grammatical organization of human languages is accounted for in terms of a set of principles internal to the grammar itself, which have psychological reality. The recourse to internal explanation is traditionally regarded as one of the most distinguishing features of the Chomskyan approach to linguistic universals, as opposed to other approaches such as the Greenbergian approach or functionalist approaches in general, which account for linguistic universals in terms of principles external to the grammatical system itself and ultimately rooted in semantics, pragmatics, and language use. It should however be noted that, as is observed by Newmeyer (1998: 104–105), linguistic universals in the Chomskyan approach are ultimately motivated in terms of innateness, and innateness is also external to the grammatical system as such.

The other consequence of the toolkit nature of Universal Grammar is that the mental representation of linguistic universals includes a number of options that are not actually implemented in the grammar of individual languages. Since it is assumed that the language learner cannot construct the target grammar on the basis of the external input and that any learner can learn any language, it follows that the whole range of possible options for a grammar must be prespecified in the learner's mind, even if not all of those options will actually be realized in the target grammar. As a result, it may be assumed that a particular mechanism ascribed to Universal Grammar

is indeed a universal of language even if it is not manifested in individual languages. For example, the fact that some languages are head-initial does not mean that the value 'head-final' is not specified in the mind of speakers of those languages; it just means that this option is not implemented in the grammar of the relevant languages.

This brings us to another major distinguishing feature of the Chomskyan approach: Universals are motivated in terms of theory-internal criteria rather than empirical cross-linguistic investigation. In the Greenbergian approach, universals are data-driven, and they are established based on large language samples. In the Chomskyan approach, on the other hand, universals are primarily established on the basis of theory-internal considerations. The rationale behind this approach is that if it can be demonstrated that a property of a single language cannot be learned, that property has to be part of the innate endowment of the language learner, and therefore it is universal. Arguments for the innate, and therefore universal, status of a particular principle usually include the fact that the principle is so abstract or complex that it couldn't be learned inductively, the fact that the principle appears at an extremely early stage of child development, and the fact that the principle cannot plausibly be attributed to any aspect of the external input received by the language learner (Newmeyer, 1998: 85).

A consequence of the theory-driven status of language universals in the Chomskyan approach is that universals are established on the basis of in-depth investigation of individual languages rather than cross-linguistic comparison as such. The Principles and Parameters version of generative grammar has indeed pointed out the necessity of cross-linguistic comparison (see, e.g., Chomsky, 1995). Other generative theories, such as Lexical-Functional Grammar (Bresnan, 2001), Auto-Lexical Syntax (Sadock, 1991), and Role and Reference Grammar (Van Valin and LaPolla, 1997) have also developed a machinery designed to account for the wide variety of syntactic phenomena found across languages. As is observed by Hawkins (1988: 87–88), however, emphasis still lies on theory in the Principles and Parameters paradigm, so that first a theory is formulated, usually on the basis of a well-known language such as English, and then it is tested and refined by looking at whatever languages seem appropriate. This is in contrast to the Greenbergian approach, where universals are descriptions of statistical tendencies revealed by cross-linguistic investigation.

Linguistic Universals, Greenbergian

S Cristofaro, University of Pavia, Pavia, Italy

© 2006 Elsevier Ltd. All rights reserved.

The major assumption underlying the Greenbergian, or typological, approach to the study of language, and the so-called functional-typological approach that originated from it (Croft, 2003: Ch. 1), is that the structural variation displayed by the world's languages is ordered and can be described in terms of linguistic universals, that is, a set of constraints or restrictive principles having universal validity (Greenberg 1963/1966; Greenberg *et al.*, 1978). These constraints are of two types. On the one hand are constraints stating that all languages behave in the same way with respect to the distribution of single features, such as the presence or absence of vowels. These constraints state that the relevant feature is either universally present or universally absent in the world's languages, leaving no room for variation. These constraints go under the name of 'unrestricted universals' and are comparable to the universal principles postulated in the Chomskyan approach (*see* **Linguistic Universals, Chomskyan**). A classical example of an unrestricted universal is the statement that all languages have vowels (see, e.g., Croft, 2003: 52).

On the other hand are constraints concerning the correlation between different features. These constraints state that all languages that exhibit a feature A also exhibit a feature B. For instance, languages having nasal vowels also have corresponding oral vowels (Croft, 2003: 54). Of course, since the relevant feature need not be present in a language, these constraints cannot be regarded as universal in the sense stated above: languages do not display uniformity with respect to the relevant features. For instance, there may be languages with both oral and nasal vowels, or languages with oral vowels only. However, the restrictive principle excludes the existence of languages with nasal vowels but no corresponding oral vowels. In this case, the restrictive principle describes a pattern of variation. Languages behave in different ways with respect to the distribution of the relevant features, but their variation must obey the limits set by the restrictive principle. What is universal in this case, then, is the fact that languages have to conform to the same pattern. However, the pattern itself allows a certain amount of variation.

This second type of language universals goes under the name of 'implicational universals.' Implicational universals state a dependency between logically independent grammatical parameters. As such, they may be seen as an application of propositional logic to typology. A standard implicational universal of the form A → B covers four logically possible types: A & B, ~A & B, ~A & ~B, and A & ~B. Of these, the former three types are allowed by the implication, while the fourth is excluded.

Any dependency relation between logically independent grammatical parameters may thus be described by means of an implication formulated in such a way that the allowed types correspond to the actually attested ones and the prohibited ones are actually unattested. For example, cross-linguistic investigation shows that if relative clauses (Rel) precede the noun (N) in a language, then demonstratives (Dem) also precede the noun. This pattern covers three actually occurring types, RelN & DemN, NRel & NDem, NRel & DemN, and an unattested one, RelN & NDem. This is schematized in Table 1 (+ = attested; − = unattested).

The distribution of attested and unattested combinations in this case makes it possible to draw the implication 'RelN → DemN,' which predicts the occurrence of the attested types and excludes the unattested one, just as in Table 1.

In the last decades, typological research has accumulated a considerable body of evidence for implicational universals in phonology and morphosyntax, concerning, for example, word order, alignment patterns, parts of speech, animacy, and grammatical relations (see standard textbooks in typology such as Comrie, 1989 or Croft, 2003 for detailed treatment of these issues and relevant literature). In particular, individual implications turn out to be combinable in chains, or hierarchies, of the form:

(1) A → B & B → C & . . .

In implicational hierarchies, the consequence of each implication is the antecedent of the following one. In current typological practice, these implicational hierarchies are indicated in the form

(2) . . . C > B > A

The predictive power of implicational hierarchies is very high. If any term involved in the hierarchy is present, then all the terms to the left of it on the chain must be present. This allows for multiple predictions based on a single assumption. On the other

Table 1 Implicational universals: order of noun, demonstrative, and relative clause

	DemN	*NDem*
RelN	+	−
NRel	+	+

(Croft, 2003: 54).

hand, if any term involved in the hierarchy is absent, then all the terms to the right of it on the chain must be absent, too. This excludes a large number of language types, and the more implications involved in the chain, the more language types excluded. This is why typological research has focused on the individuation of cross-linguistic hierarchies, such as the Accessibility Hierarchy for relativization (Keenan and Comrie, 1977), the hierarchies for number, animacy, and grammatical relations (these are described in detail in Croft, 2003: Ch. 5), as well as Givón's Binding Hierarchy for complementation (Givón, 1980).

In contrast to the Chomskyan approach, in which linguistic universals have psychological reality and are in themselves explanatory principles motivating language structure, typological universals are primarily meant as generalizations resulting from empirical cross-linguistic investigation that describe statistically significant distributions of particular phenomena (see on this point Newmeyer, 1998: Ch. 6; Newmeyer, 2004). This has a number of important consequences. First, cross-linguistic comparison plays a crucial role in typological research, because universals can only be established through cross-linguistic comparison and must be established on the basis of statistically relevant patterns. As a result, considerable attention has been devoted to issues such as sampling methods, the statistical significance of individual putative universals (see, e.g., Dryer, 1992; and Rijkhoff and Bakker, 1998), and criteria to consistently identify the phenomena under investigation from one language to the other (Croft, 2003: Ch. 1).

The patterns described by language universals are in themselves in need of explanation. In the typological approach, universals are usually accounted for in terms of functional factors, that is, semantic, pragmatic, processing, or frequency factors. These explanations are usually regarded as external explanations, as opposed to the explanations usually invoked within the generative paradigm, which are internal to the grammatical system. Unlike language universals as such, at least some of the functional principles invoked in the typological approach are taken to have psychological reality (see, among others, Croft, 2001).

An example of functional explanation is provided by the various processing and frequency factors that have been proposed for what is perhaps the best-known typological hierarchy, Keenan and Comrie's (1977) Accessibility Hierarchy for relativization:

(3) Subject > Direct object > Indirect Object > Oblique > Genitive > Object of comparison

This hierarchy states that if a language can form relative clauses on any syntactic role on the hierarchy, then it can form relative clauses on all syntactic roles to the left. Keenan and Comrie's original explanation for this hierarchy is grounded on psychological ease of comprehension. The lower a role is on the Accessibility Hierarchy, the harder it is to understand relative clauses formed on that role. The underlying assumption is that if the speakers of a language are able to process relative clauses formed on a more difficult role, they are able to process relative clauses formed on less difficult roles. A similar analysis has been proposed by Hawkins (1994).

On the other hand, Fox (1987) accounts for the Accessibility Hierarchy in discourse rather than psychological/processing terms. Relying on a corpus of spoken English data, she claims that the roles that are actually most accessible to relativization are intransitive subject and direct object. This is because the primary discourse function of relative clauses is to situate the referent that is being introduced as a relevant part of the ongoing discourse. This is typically done by means of relative clauses formed on subjects of intransitive verbs or direct objects. So this type of relative clause is the most frequent relative clause type at the discourse level, and this accounts for why the relevant syntactic roles are more accessible to relativization.

Other implicational patterns have been explained in semantic (rather than processing or frequency) terms. For example, cross-linguistic investigation shows that if inalienable possession is expressed by constructions involving a certain distance between morphemes, then alienable possession will be expressed by constructions involving at least the same distance between morphemes. Haiman (1983, 1985) accounts for this pattern in terms of an iconic principle, whereby greater closeness between particular concepts (as manifested in the relationship between possessor and possessum in inalienable possession) is reflected by greater formal closeness between the linguistic elements expressing these concepts.

In some cases, it has been suggested that the explanation for a particular implicational pattern is diachronic and that functional principles only play an indirect role. For example, a bidirectional implication (logical equivalence) exists such that if a language has prepositions, then it has noun-genitive order, and if it has postpositions, then it has genitive-noun order (see, among others, Croft, 2003: 58). This can be accounted for in terms of Hawkins's (1983) principle of Cross-Category Harmony (which is ultimately motivated in terms of processing ease). Nouns and adposition belong to the same category, in that they are heads of their phrases, so the correlation between the order of adpositional constructions and the order of genitival constructions reflects a general principle

whereby modifiers are always located on the same side of the head. Bybee (1988) argues, however, that the correlation is actually motivated in diachronic terms: adpositional constructions typically originate from genitival constructions, and they maintain the order of genitival constructions. In this case, Bybee argues, functional principles may be invoked to account for why adpositional constructions develop from genitival constructions in the first place, but no functional principle can actually be invoked to account for the word order correlations between the two constructions.

It should finally be observed that a widespread assumption in the typological approach is that the various language types allowed by implicational universals reflect different functional principles, and the competition between the various functional principles determines cross-linguistic variation (Du Bois, 1985). For example, an implicational pattern exists such that if the singular is expressed by a certain number of morphemes, then the plural will be expressed by at least as many morphemes. This is usually explained in terms of an economic principle, whereby the singular is the most frequent category at the discourse level and therefore need not be expressed overtly. One such explanation accounts for the existence of languages in which the singular is zero-marked and the plural is marked overtly. However, the implicational pattern also allows for languages in which both singular and plural are expressed overtly. These languages reflect an iconic principle whereby all aspects of conceptual structure (in this case, the values 'singular' and 'plural') are expressed overtly (Croft, 2003). The implicational pattern allows for both language types, but the two language types reflect competing functional principles, each prevailing in different languages. The competition between the different principles is what determines cross-linguistic variation, as described by the implicational pattern itself.

A common description of linguistics is that it is the 'scientific study of language.' This might seem to be a loose or metaphorical use since the subject matter of linguistics is quite different from what are often thought of as the 'hard' sciences such as physics or chemistry. But linguists are engaged in a process of inquiry that aims to discover facts about the world we live in, and so their work shares important properties of other sciences. Some work in linguistics (e.g., acoustic phonetics) resembles the 'hard' sciences in

History of Linguistics: Discipline of Linguistics

Introduction

Language makes us human.

Whatever we do, language is central to our lives, and the use of language underpins the study of every other discipline. Understanding language gives us insight into ourselves and a tool for the investigation of the rest of the universe. Martians and dolphins, bonobos and bees, may be just as intelligent, cute, adept at social organization, and morally worthwhile, but they don't share our language, they don't speak 'human'. Linguistics, the scientific study of language, seeks to describe and explain this human faculty. It is concerned with three things: discovering precisely what it means to 'know a language'; providing techniques for describing this knowledge; and explaining why our knowledge takes the form it does.

These concerns may seem too obvious to need discussing, but the complexity of our knowledge of language becomes strikingly apparent when we see someone lose their language after they have had a stroke, or when we observe an infant who has yet to acquire the faculty that we deploy so easily. To understand these three concerns, we need a theory, and that is what linguistics provides.

The Meaning of 'Language'

That linguistics is 'the scientific study of language' has become a cliché, but what it means to be 'scientific' may not always be obvious, and what people mean when they use the word 'language' varies from occasion to occasion. Consideration of what is involved in being scientific is deferred until later in the essay, for now it suffices to observe that only a few aspects of language have been illuminated by theoretical (scientific) linguistics, so there are many areas where it has little, if anything, helpful to say. The situation is akin to that in biology, viewed as the science of living things. Despite their importance to us, biology has nothing to say about the definition of pets; similarly, despite their relevance to us, linguistics has nothing to say about the definition of dialects.

In everyday usage, 'language' is used differently, depending on whether it is construed as a property of the individual, of society, of the species, or as an autonomous entity in the world. Linguists working in the tradition of 'generative' grammar, the framework that has dominated linguistics for the last 50 years, argue that an 'individual' approach to language is logically prior to any other, but in principle we have the possible domains shown in (1), each suggesting different kinds of questions:

(1) Language and the Individual
Language and the Brain
Language and Society
Language and the Species
Language and Literature
Language and the World

Looking at 'Language and the Individual', the central question raised is 'what constitutes our "knowledge of language"?' What properties or attributes does one have to have to be correctly described

as a speaker of English, or Burmese, or any other 'natural language' – the term linguists use to refer to languages naturally acquired and spoken by humans, as opposed to the 'artificial' languages of logic or computing? An extension of this question is how and where knowledge of language is represented in the brain, and what mechanisms need to be postulated to enable us to account for our use of this knowledge. Neurolinguistics is an area of remarkable growth, supported by technological advances in imaging.

Under 'Language and Society', sociolinguists raise questions such as 'What are the social variants (class, age, gender, power) that determine, or correlate with, the use of particular forms of the language?' A woman might use some pronunciations or grammatical constructions with statistically significantly greater frequency than a man of the same age, or a female of a different generation. For the world's multilingual majority, social considerations may even determine which language is used in specific situations. A Swiss from Graubünden might use Romansh at home, Swiss German at work, and High German at a conference.

Looking at 'Language and the Species', we might be preoccupied with the puzzle that all human children learn their first language with seeming effortlessness, while the young of other species, however intelligent, show minimal such ability. Linguists, and researchers in related fields, investigate not only whether this claim to uniqueness is indeed true but, if it is, how the faculty evolved.

When we turn to the relation between Language and Literature, we confront several issues: 'What is literary form?'; that is, what are the linguistic properties that make something a novel or a novella, a sonnet or an epic? How are literary effects achieved? What are the linguistic characteristics of a particular style?

Looking at 'Language and the World' raises issues of three different kinds. First, how does language relates to things outside the head? That the word 'London' refers to the capital of the United Kingdom is innocuous enough as an informal claim, but it raises interesting, and vexed, philosophical questions. The debate revolves around the status of language as a property of an individual, rather than as an entity with independent existence. This 'external' notion of language is presupposed by those who write irate letters to the press, inveighing against split infinitives, and lamenting the fact that our language is becoming degenerate, either because of the sloppiness of modern youth, the pernicious influence of text messaging, or the role of multiculturalism. The third issue is in many ways the most obvious and the most puzzling: Why are there so many languages? Why does 'human' have so many dialects?

Knowledge of Language

The generativist claim that study of the individual's knowledge of language must be the first or exclusive focus of a scientific linguistics is controversial; that it is a possible, indeed necessary, focus is not seriously in doubt. This individualistic claim implies that linguistics is a branch of psychology, ultimately biology, rather than, say, of sociology. This is not to deny that there are interesting domains of knowledge that take the social conditions of language use as their central focus; it is rather to claim that there is a psychological enterprise which looks at one branch of human cognition and which lends itself to rigorous investigation and, moreover, that it is logically prior to looking at the exploitation of this knowledge in society. This focus on knowledge is highlighted in the claim that the subject of linguistics is 'I-language', rather than 'E-language', where the 'I' stand for *i*nternal to a particular *i*ndividual, and 'E' stands for *e*xternal (to the mind of the individual). A corollary of this orientation is that the descriptions that linguists devise are said to be 'psychologically real', where this is not a claim about psychological experimentation or the kind of evidence used in formulating particular linguistic hypotheses, but is simply the claim that we are investigating the human mind and that current theory is the closest approximation to the truth that we have.

The mind is ultimately a product of the brain (and other systems), and evidence about the mental can sometimes be gleaned from studies of the neural. In general, however, linguists remain agnostic about the details of the relation between the mind and the brain (frequently referring simply to the 'mind/brain'). That is, we devise theories of a sub-part of human knowledge, but whether that knowledge is localized in the temporal lobe of the left hemisphere, or is distributed throughout the brain, or whatever, is less important. This is not because of lack of interest, but simply because – at present – theories of neural structure are too embryonic to cast much light on linguistic generalizations. Different languages allow different word orders, so that Japanese puts the verb at the end of the sentence and English puts it in the middle. Linguistic theory must provide the means for describing and ultimately explaining this fact, but at present we have no inkling of how the difference between a Japanese and an English speaker might be neurally implemented, so the neurological structure of (this bit of) the language faculty is still a closed book.

What do you have to know to count as a 'speaker' of a language? If you say you speak English, it implies that you understand English, too. The point may

seem trivial, but knowledge of language is neutral between speaking and hearing; both activities draw on the same fund of knowledge. There is no known illness or accident which leaves you able to speak only English and understand only Portuguese, for instance. This is not to deny that you may be better at talking than listening; or that you may suffer brain damage that leaves you unable to speak while you remain perfectly able to understand. A particularly poignant example of this is provided by Bauby's autobiographical account of 'locked-in' syndrome, where a stroke left the author speechless, but with his language and his ability to understand intact. In normal, non-pathological, cases, however, your ability to *utter* (2a):

(2a) Giraffes have long necks
(2b) Giraffes have necks long

involves the same ability that enables you to *understand* (2a), and also to judge that someone who mistakenly says (2b) has got it wrong. The implication of this observation is that the primary focus of linguistics is on characterizing this neutral knowledge, rather than the mechanisms of speaking, hearing, and judging that are parasitic on it. In other words, linguistics is (largely) about one form of cognition, and only secondarily about the deployment of that cognitive ability. In the standard terminology, this is known as the 'competence-performance' distinction. Your knowledge of language (your competence) underlies your ability to speak, to understand, and to give judgements of well- or ill-formedness (your performance). You may be knocked unconscious and be temporarily unable to speak or understand, but your knowledge typically remains intact – you have competence with no ability for performance. The converse situation, in which you could perform in the absence of any competence, does not occur, though it may characterize the 'linguistic' capabilities of the average parrot, which may be able to utter entertaining sentences of what sounds like English, but presumably without the knowledge of English grammar that underlies our abilities.

To count as a speaker of English, you need first to know a large number of words: not just nouns, verbs, and adjectives – words such as *cat* and *go* and *pretty*, whose meaning is relatively transparent, but items such as *the, under,* and *however*, whose meaning and use are less easy to specify. Of course, not everyone has the same vocabulary: I may know technical terms in linguistics that you are ignorant of, and you may be familiar with words pertaining to reggae or arachnology that I don't know, but if either of us were ignorant of words such as *mother* or *and*, people might be justifiably reluctant to classify us as speakers of English.

In addition to knowing the words of a language, you need to know what to do with those words – you need to know the grammar. Our knowledge of language falls into two compartments – the vocabulary (or 'lexicon') and the 'computations' we can carry out using that vocabulary. This computational system, comprising syntax and morphology, is surprisingly complex, and enables us to produce baroque examples such as Chomsky's (1995: 88) *Who do you wonder whether John said solved the problem?* Such sentences are of marginal acceptability and citing them may strain the tolerance of outsiders, but this marginal status may itself provide crucial evidence for or against some theoretical claim concerning our knowledge. Henceforth, I shall assume that you and I have the same I-language, abstracting away from differences in vocabulary and grammar. Fortunately, it's enough for the present purposes to look at the more basic, but nonetheless rich and surprising, knowledge we have of words as simple as *be* and *the*. Consider the examples that follow, which illustrate a wide range of things you know, even if you weren't previously aware of knowing them. It's self-evident that *is* and *have* mean different things, as shown in (3), but sometimes they seem to be used interchangeably as in (4):

(3a) Tom is a problem
(3b) Tom has a problem

(4a) Tim is yet to win the Booker prize
(4b) Tim has yet to win the Booker prize

How is it that something as basic as *is* can sometimes get the same interpretation as *has* and sometimes a different one? Or consider the so-called definite article (*the*), which is often said to mark the distinction between entities which are already familiar and those which are new, as in (5a) and (5b) respectively:

(5a) My friend likes the penguins
(5b) My friend likes penguins
